## Abstract

The objective of this thesis is to analyze the potential role of hydrogen for Norway in the transition to a zero-emission society. The main sector of focus is the transport sector. Here, socioeconomic analyses are carried out to increase understanding of the best usage of hydrogen in this sector. The most relevant hydrogen production technologies are also analyzed so as to provide TiZir Titanium & Iron with more information on the long-term implications of their choice of technology solution in their transition from using coal to using hydrogen as a chemical component in their production line.

In this thesis, the implications of ITE's projections of vehicle stocks developments are analyzed socioeconomically. The net present values of investments into hydrogen passenger vehicles, cargo vans, heavy-duty trucks and buses are analyzed and compared with those of electric vehicles. It is found that the best investments regarding hydrogen is the sector of heavy-duty trucks, followed by cargo vans.

Hydrogen production with steam methane reforming (SMR) and water electrolysis are analyzed and compared with each other. SMR is found to not be socioeconomically viable, not attractive due to low CO<sub>2</sub>-taxes and there is uncertainty as to whether the technology is good enough or not. It is concluded in this thesis that hydrogen produced with fossil fuels at best is as good as hydrogen produced with energy from renewable sources. Nonetheless, it is strongly suggested that further development of this technology is pursued in light of IPCC's claim that CCS is necessary for global warming to be limited to 2 °C.

The implication of ITE's projections of vehicle stocks developments on Norway's ability to reach its climate goals are analyzed. It is found to only amount to 13 % GHG reductions in the period 2017-2030 with respect to 1990-levels. If the transport sector is to reduce emission by 40 % or more, then annual emissions must be reduced by at least an additional 2.1 Mt CO<sub>2</sub>-equivalents by 2030 in this sector. It is concluded that Norway's climate goals will not be met if escalated actions are not taken.

## Samandrag

Føremålet med denne masteroppgåva er å analysere den potensielle rolla hydrogen kan spele for Noreg i overgangen til eit nullutsleppsamfunn. Sektoren som er lagt mest vekt på er transportsektoren. Her er samfunnsøkonomiske analyser utført for å auke forståinga for best mogleg bruk av hydrogen i denne sektoren. Dei mest relevante hydrogenproduksjonsteknologiane er også analysert for å gi TiZir Titanium & Iron meir informasjon om dei langsiktige verknadane av valget av teknologiløysing dei tek i overgangen frå bruk av kol til bruk av hydrogen som kjemiske komponent i deira produksjonslinje.

I denne masteroppgåva er verknadene av Transportøkonomisk institutt (TØI) sine framskrivingar av køyretøybestanden analysert samfunnsøkonomisk. Noverdiane av investeringane i hydrogenpersonbilar, -varebilar, -lastebilar og -bussar er analysert og samanlikna med dei tilsvarande noverdiane til elektriske køyretøy. Det er funne at den beste investeringa for hydrogen er i lastebilsektoren, etterfylgt av varebilsektoren.

Hydrogenproduksjon ved dampreforming av naturgass (SMR) og vasselektrolyse er analysert og samanlikna med kvarandre. SMR er ikkje samfunnsøkonomisk levedyktig, ikkje bedriftsøkonomisk attraktivt grunna låg CO<sub>2</sub>-avgift og det er usikkert om teknologien er god nok eller ikkje. I denne masteroppgåva er det konkludert med at hydrogen produsert med fossile kjelder kun har potensiale til å vere like bra som hydrogen produsert med energi frå fornybare kjelder. På trass av dette er det sterkt anbefalt at ein held fram med utvikling av denne teknologien grunna IPCC sine konklusjonar om at karbonfangst og -lagring er naudsam for å halde global oppvarming under 2 °C.

Verknadene køyretøybestandsutviklinga framskrive av TØI vil ha på Noreg si evne til å nå klimamåla er analysert. I denne masteroppgåva er det estimert at ein i transportsektoren kun oppnår ein klimagassreduksjon på 13 % i perioden 2017-2030 samanlikna med nivået i 1990. Viss transportsektoren skal redusere sine klimagassutslepp med 40 % eller meir, må årlege utslepp reduserast med minst 2.1 Mt CO<sub>2</sub>-ekvivalentar innan 2030 i denne sektoren. Det er konkludert med at Noreg sine klimamål ikkje vert haldne viss auka innsats ikkje vert iverksett.

## Acknowledgements

This thesis has been realized with knowledgeable support from many actors in the industry. Special thanks are given to supervisors Norbert Lømmen from the Faculty of Engineering and Business Administration at the Western Norway University of Applied Sciences and Vegard Frihammer, Green Executive Officer at Greenstat AS for their invaluable support in the process.

Additional thanks is given to Kristian Ringen Fauske, Green Financial Analyst at Greenstat AS, for his advice and input on the economic analyses.

# 1 Introduction

Norway has, since the mid-1960s, heavily invested in the fossil fuel industry (1). These investments have laid the foundation for the state of welfare seen in Norway today. With the world leaders meeting in Paris reaching an agreement stating all countries are to work towards limiting global warming to 2 °C (2), and Norway taking upon itself to reduce emissions by 40 % from 1990-levels by 2030 (2), Norway faces challenging times. More than 1/3 of Norway's export income comes from the fossil fuel industry (3). Norway exports more than 2 000 TWh worth of fossil fuels to international markets (4). Emissions must be reduced by 22.7 million tons CO<sub>2</sub>-equivalents if Norway is to hold its climate goals (5), but how are these major changes to be done? Which energy sources is Norway to rely on? What will happen to the fossil fuel industry? If the fossil fuel industry dies, how is Norway going to maintain the state of welfare it experiences today? Where can emissions be cut most cost efficiently? How fast can emissions be cut? Can emissions be cut while the fossil fuel industry simultaneously thrives?

In this report, it is analyzed how hydrogen can be utilized towards reaching the climate goals Norway has set for itself. Various alternative production methods and uses of hydrogen are compared with other solutions commercially available today to get an idea of whether hydrogen or another solution should be implemented to solve a certain issue Norway either faces today or will face in the future related to tackling climate change and reaching Norway's climate goals.

When evaluating which solution is better equipped to solve specific issues for Norway today and in the future, socioeconomic net present values are estimated.

In this report, potential usage of hydrogen in a specific case is also analyzed. This case is TiZir's planned transition from using coal as chemical component in their production line for titanium and iron to using hydrogen. Here, communication is established with TiZir to reach an understanding of their most valued factors when deciding between the alternative methods of hydrogen production. These factors are analyzed, acting as decision support for their evaluation of the available alternatives.

Political leaders in the Norwegian society have requested methods for estimating the government's budget's impact on national GHG reductions (6). Part of this request is answered in this master thesis.

## 2 Theory

In this chapter, various hydrogen production technologies, usage of hydrogen and distribution of hydrogen are presented. Additionally, information on carbon capture and storage, social costs of emissions and national forecast for vehicle stocks are presented.

### 2.1 Production of hydrogen

Globally, hydrogen production and consumption amounts to approximately 50 million tons per year (7).

Hydrogen is, as of 2016, produced mainly from natural gas steam reforming without CCS, accounting for 48 % of all hydrogen production. The remainder comes from petroleum production during the refining process accounting for 30 %, coal based hydrogen represents 18 % and the rest, 4 %, is hydrogen produced with electrolysis (8).

In the following chapter, the most common production technologies will be presented in detail.

#### 2.1.1 Steam reforming method

The steam reforming method consists of two steps. In the first step, water vapor and the hydrocarbons react assisted by a nickel catalyst at around 800 °C (9). Meanwhile, Nikolaidis et al. claim that the temperatures are closer to 900 °C, with pressures up to 3.5 MPa and steam-to-carbon ratios of 3.5 (10). The fundamental reaction equation of the steam reforming method is

*Equation 1: Chemical equation for the reformer in the steam-methane reforming process*

In the next step in the process, the remaining carbon monoxide reacts with more water vapor in the “water gas shift reactor” assisted by a new catalyst, this time copper or iron, and at a temperature of approximately 500 °C (9).

*Equation 2: Chemical equation for the WGS reactor in the steam-methane reforming process*

Other gases used as raw materials are ethane, propane, butane, pentane and light and heavy naphtha (10). After the reformers, the mass flow consists mainly of hydrogen and carbon dioxide. Either, the CO<sub>2</sub> is removed and the remaining gas goes through a methanation process in order to recycle the remainder of the carbon monoxide. Alternatively, the mixture passes through a pressure swing adsorption unit which separates the carbon dioxide from the hydrogen. Hydrogen with a very high purity can be achieved. According to Rönsch et al (11), there are three CO<sub>2</sub> methanation technologies

available on the market. These are namely Outotec, Etogas and MAN methanation, which are all fixed-bed reactor concepts (11). The chemical reaction occurring in the methanator is as follows

*Equation 3: Chemical equation for the methanator in the steam-methane reforming process*

### 2.1.2 Partial oxidation method

The partial oxidation (POX) method is similar to the steam methane reforming method. However, here also oxygen in addition to water is mixed with the hydrocarbons. This is better illustrated with the chemical equations of the reformer

*Equation 4: Chemical equation for the catalytic part of the reformer in the partial oxidation method*

*Equation 5: Chemical equation for the non-catalytic part of the reformer in the partial oxidation method*

Equation 2 and Equation 3 give the chemical equations of the water gas shift (WGS) reactor and methanator, respectively. The reformation process is divided into two subparts. The first part, as shown in Equation 4, is a catalytic process occurring at about 950 °C, which can use feedstock ranging from methane to naphtha. The second part, as shown in Equation 5, is a non-catalytic process occurring at 1150-1315 °C according to Nikolaidis and Poullikkas with feedstock being hydrocarbons including methane, heavy oil and coal (10).

Nikolaidis and Poullikkas claim POX to be the most appropriate technology for production of hydrogen from heavier feedstock, such as heavy oil residues and coal. However, due to the low hydrogen content of heavy oil and coal, water supplies respectively 69 and 83 % of the hydrogen produced.

### 2.1.3 Autothermal reforming method

The autothermal reforming method (ATR) essentially is a combination of the steam methane reforming method and the partial oxidation method. In ATR, the heat required for the endothermic steam reformation is provided by the exothermic partial oxidation (10). This means that the reforming and oxidation reactions occur simultaneously due to steam and air being injected into the reformer at the same time. Nikolaidis et al. (10) claim the optimum operating temperature for ATR hydrogen production from methane to be 700 °C.

#### 2.1.4 Hydrocarbon pyrolysis

Unlike the previously discussed fossil fuel methods of hydrogen production, hydrogen from hydrocarbon pyrolysis comes solely from the hydrocarbons (12). This occurs by decomposition of the hydrocarbons through heating in an inert atmosphere. The chemical reaction is given in Equation 6.

Equation 6: Hydrocarbon pyrolysis chemical reaction

Pyrolysis of methane occurs at temperatures up to 980 °C and atmospheric pressures (10). As this process does not require carbon capture and sequestration, the hydrogen production cost for large plants is 25-30 % lower than that of the processes of steam conversion or partial oxidation.

#### 2.1.5 Thermochemical processes based on biomass

Thermochemical processes based on biomass consist mainly of pyrolysis and gasification. Pyrolysis of biomass and hydrocarbons are rather similar. However, since biomass generally carry a significant amount of oxygen, the chemical reaction becomes somewhat different (13):

Equation 7: General chemical equation for thermochemical production of hydrogen based on biomass (13)

The production cost of hydrogen by pyrolysis is expected to be in the range of \$ 1.25-2.20/kg hydrogen, depending on the facility size and biomass type (10).

Gasification of biomass usually undergoes one of the following reactions in order to produce hydrogen:

Equation 8: General chemical equation for gasification of biomass using water (10)

Equation 9: General chemical equation for gasification of biomass using steam (10)

Operating temperatures and pressures of gasification range from 500-1 400 °C and atmospheric to 33 bar, respectively, depending on plant scale (10). The best-known reactors utilized for biomass gasification are fixed bed and fluidized bed gasifiers. Fixed bed gasifiers have a bed of solid fuel particles through which the gas moves with low velocity. Meanwhile, the fluidized bed gasifier implies that the gas entering has such a high velocity that the bed acts as a fluid, causing great mixture of the gas and the solids.

### 2.1.6 Biological processes based on biomass

The main biological hydrogen production processes are photolysis and fermentation. Photolysis utilizes the same principles as found in photosynthesis, but is in this case adapted to the generation of hydrogen gas as shown in Equation 10.

*Equation 10: Overall chemical reaction of photolysis using algae*

In traditional photosynthesis, only CO<sub>2</sub> reduction takes place. This is due to the hydrogen-forming enzyme, hydrogenase, being absent. The green algae require anaerobic conditions and darkness in order to activate and synthesize their hydrogenase enzyme (14). When this is achieved, some hydrogen is produced. Returning the green algae to light, still under anaerobic conditions, results in increased hydrogen production.

Fermentation is an oxidation process of incomplete combustion which can be found at bacteria and mushrooms (15). It is a conversion of organic compounds, such as organic waste and biomass materials, to hydrogen in anaerobic conditions. The chemical equation of one such fermentation process is given in Equation 11 (16).

*Equation 11: Chemical equation for fermentation of glucose (16)*

### 2.1.7 Water electrolysis

Most studies done on hydrogen production from electrolysis is done with electricity supplied from a photovoltaic system or wind farm, usually on quite a small scale. For hydrogen production facilities in Norway, where 97 percent of electricity production is based on renewable resources, the aspect of carbon capture and sequestration is unnecessary to consider. The immediately economically most viable solution in Norway is to connect one's hydrogen production facility to a nearby hydropower facility or simply to the power grid to meet electricity demand.

Water electrolysis can be simplified to consist of the following chemical reaction.

*Equation 12: General chemical reaction for water electrolysis*

During the electrolysis, the positive ions are reduced by adopting electrons from the negative electrode, the cathode. Simultaneously, the negative ions are oxidized by giving electrons to the positive electrode, the anode.

Different electrolyzers function in slightly different ways. This is mainly due to the different types of electrolyte material involved.

#### *Proton Exchange Membrane electrolyzer*

In the proton exchange membrane (PEM) electrolyzer, also known as the polymer electrolyte membrane (PEM) electrolyzer, the electrolyte is a solid plastic material (17).

In the PEM electrolyzer, oxygen and protons are formed by the water's dissociation reaction at the anode. The protons are allowed through the membrane as the name indicates, while the electrons flow through an external circuit powered by a power supply. At the cathode, the hydrogen ions and electrons recombine, forming hydrogen gas.

The usage of PEM electrolyzers have increased of late, some of which due to the following properties (7):

- PEM electrolyzers can operate under high current densities. Especially for systems utilizing dynamic energy sources such as wind and solar energy, this can lead to reduced operating costs.
- Due to PEM's area demand being lower than alkaline's, PEM's economic viability increases as production demand of hydrogen increases. In cases where available area is constrained, PEM will be especially advantageous
- Since PEM electrolyzers usually are pressurized, further compression of the hydrogen for distribution or storage is less energy consuming and as such less cost intensive than otherwise.
- PEM electrolyzers produce hydrogen of very high purity, which is a demand for many applications.

The greatest disadvantage of the PEM electrolyzer is its cost (7). Some of this is due to the PEM technology being rather young (7), and the industry expects the cost of PEM electrolyzers to approach that of alkaline electrolyzers over a period of 5-10 years. The reason for this being mainly potential for increased stack area, reducing usage of materials and area demand which again reduces costs.

The dominating suppliers of PEM electrolyzers on the European market are Hydrogenics, ITM Power, Air Liquide and Siemens (7). For instance, ITM Power recently announced they will establish their first hydrogen station in collaboration with Shell in the United Kingdom (18).

### Alkaline electrolyzer

While PEM electrolyzers transport protons between the cathode and the anode, alkaline electrolyzers transport hydroxide ions,  $\text{OH}^-$ . The formation of hydrogen gas at the cathode and oxygen gas at the anode is shown in Equation 13 and Equation 14, respectively.

*Equation 13: Hydrogen production in an alkaline electrolyzer*

*Equation 14: Oxidation of the hydroxide*

The alkaline technology has reached state of the art-level (13) and electrolyzers with a liquid alkaline solution of sodium or potassium hydroxide as the electrolyte have been commercially available for many years (17).

The commercially available alkaline electrolyzers today have an average energy consumption of 4.5 kWh/Nm<sup>3</sup> hydrogen, giving an electric efficiency of 67 % (7).

The most renowned supplier of alkaline electrolyzer hydrogen production plants today is NEL, which are well on their way of supplying the market with plug-and-play hydrogen modules (19), both for production and for fueling (20).

According to a study done by Gahleitner (21), the average nominal efficiency of the alkaline electrolyzers is 70 %. This is based on the higher heating value. Equation 15 shows the definition of the energy efficiency.

$$\eta_{\text{electrolyzer}} = \frac{\dot{V}_{\text{H}_2} \cdot \text{HHV}}{P_{\text{el}}}$$

*Equation 15: Energy efficiency of electrolyzers used in the Gahleitner study (21)*

Here  $\dot{V}_{\text{H}_2}$  is the nominal capacity,  $P_{\text{el}}$  is the installed power of the electrolyzer and HHV is the higher heating value of hydrogen with 12.75 MJ/Nm<sup>3</sup> (21).

### Solid Oxide Electrolyzer Cell

The Solid Oxide Electrolyzer Cell (SOEC) conducts negatively charged oxygen ions ( $\text{O}^{2-}$ ) through its electrolyte, a solid ceramic material, at elevated temperatures (17).

At the cathode, water is split into hydrogen gas and oxygen ions as shown in Equation 16. As mentioned, the oxygen ions pass through the electrolyte to the anode, where the chemical reaction of Equation 17 occurs.

*Equation 16: SOEC reaction at the cathode*

*Equation 17: SOEC reaction at the anode*

SOEC is more advantageous compared to PEM and alkaline electrolyzers due to the fast electrochemical reactions and good ion conduction at an elevated temperature (22), leading to lower electrical energy requirements. The solid oxide membrane functions properly at about 700-800 °C, setting the standard for the SOEC operating temperature (17).

#### 2.1.8 Water thermolysis

Thermolysis of water is similar to pyrolysis of hydrocarbons. In water thermolysis, also known as single step thermal dissociation of water, water is decomposed into hydrogen and oxygen gas at very high temperatures. For example, at 3 000 K and 1 bar, the degree of dissociation is 64 % (13). Avoiding recombination of hydrogen and oxygen is a major part of this production method, and is done by separating the two gases with palladium membranes (23). Equation 18 gives the general chemical reaction equation.

*Equation 18: General chemical reaction equation for water thermolysis (23)*

## 2.2 Usage of hydrogen

In the following chapter, various areas of use for hydrogen are explained.

### 2.2.1 Production of Ammonia

About 75 % of all ammonia produced globally uses the Haber-Bosch method, where nitrogen reacts with hydrogen as shown in the following chemical reaction equation (24):

*Equation 19: Production of ammonia*

This process occurs usually at temperatures of 350-600 °C and pressures of 150-300 bar. In order to achieve a sufficient reaction rate at this temperature, an iron based catalyst is utilized. The hydrogen used in this process is made from natural gas, outcompeting the previously used facilities based on coal or water electrolysis (24).

Some ammonia is also produced by the Casale or the Claude method (24), which is principally similar to the Haber-Bosch process, but uses higher pressures.

### 2.2.2 Refineries

In refineries, hydrogen, amongst other things, is used in hydrocracking, isomerization and hydrotreating and sulphur plants (25).

In hydrocracking, heavier hydrocarbon molecules are broken down to lighter products such as petrol and diesel. Here, hydrogen combines with the chemical bonds of the cracked hydrocarbons, creating isomers with the desired characteristics.

In isomerization, paraffins, which are straight-chained hydrocarbons, are chemically rearranged to become isoparaffins, which are branched.

In hydrotreating, hydrogen is used to remove contaminants from the desired products. Mostly, the consumption of hydrogen here goes to the removal of sulfur, forming hydrogen sulfide.

### 2.2.3 Production of methanol

In the process industry, hydrogen is used in the production of methanol. The relevant chemical reaction equations are (26):

*Equation 20: Carbon monoxide and hydrogen react to methanol (26)*

*Equation 21: Carbon dioxide and hydrogen react to methanol and water (26)*

*Equation 22: Carbon monoxide and water react to carbon dioxide and hydrogen (26)*

Normally, these reactions are done at pressures of 40-120 bar and temperatures of 200-300 °C in fixed-bed reactors (26).

Catalysts typically used in such systems are mixtures of copper, zinc oxide, alumina and magnesia.

#### 2.2.4 Fuel cells

Despite the principle technology for fuel cells dating back to the British physicist W. R. Grove of 1839 who was able to develop electricity by the reaction of hydrogen and oxygen (27), it is not until today this technology looks to become commercialized.

As a fuel cell is operated in the same way as an electrolyzer, only in opposite direction, the technology will not be discussed in detail.

#### *Passenger cars*

Fuel cell electric vehicles (FCEV) are being made by numerous manufacturers at present and near future. An overview of the status as of January 2017 is shown in Table 1.

| Manufacturer | Release date | Comments                                                                                                                |
|--------------|--------------|-------------------------------------------------------------------------------------------------------------------------|
| Hyundai      | 2013         | ix35 was their first model.<br>New model due 2018                                                                       |
| Toyota/Lexus | 2015         | Mirai was their first model.<br>New models will be introduced before the Tokyo Olympics 2020                            |
| Honda        | 2016         | Clarity Fuel Cell was their first model.<br>Cooperation established with General Motors for new models from 2020        |
| Mercedes     | 2017         | GLC F-Cell plug-in, a hybrid of battery and hydrogen, coming in 2017.                                                   |
| Nissan       | -            | So far only has a prototype SOFC vehicle running on bioethanol.                                                         |
| Ford         | -            | No FCEV of their own, but co-developed Mercedes' fuel cell for the GLC model                                            |
| Mazda        | -            | Agreement of cooperation established with Toyota.                                                                       |
| Renault      | 2014         | HyKangoo ZE was their first model. This was a fuel cell battery hybrid. New models available for pre-order now.         |
| GM/Opel      | 2020         | See Honda. 119 test vehicles have been part of GM's research program since 2007. 30 of these have been Opel's vehicles. |
| Kia          | 2020         | Little information is available regarding this release. When this release will actually transpire is uncertain.         |
| BMW          | 2021         | Little information is available regarding this release. When this release will actually transpire is uncertain.         |

Table 1: Status for enrollment of fuel cell electric vehicles (28)

The list presented in Table 1 is based on a list created by the Norwegian Hydrogen Forum (28).

The oldest commercially available hydrogen vehicle being the Hyundai ix35 model, released in 2013, there has been a steep decline in sale price for hydrogen vehicles. The Hyundai ix35's cost in Norway, 2013, was 1.2 million NOK (29). Two years later the price had dropped by more than 50 %, and in 2017, through an agreement established between Hyundai, Greenstat, Hordaland County Council, Bergen City Council and CMR Prototech, more than 20 cars are being sold in the Bergen area in Norway for 400 000 NOK (30).

### Public transport: buses and trains

The development of public transport fueled by hydrogen is young of nature. The Clean Hydrogen in European Cities project (CHIC) lasted from 2010-2016 and was a flagship zero-emission bus project (31). Over the course of this project, a fleet of 54 fuel cell electric buses and hydrogen fueling stations were deployed across Europe and at one site in Canada. An overview of the deployment and specifications is given in Table 2, while statistics over the project period for the individual cities are given in Table 3:

| Bus manufacturer                      | APTS        | EvoBus Mercedes-Benz                                  | New Flyer     | Van Hool                | Wrightbus  |
|---------------------------------------|-------------|-------------------------------------------------------|---------------|-------------------------|------------|
| City of operation and number of buses | Cologne (2) | Aargau (5)<br>Bolzano (5)<br>Hamburg (4)<br>Milan (3) | Whistler (20) | Cologne (2)<br>Oslo (5) | London (8) |
| Drive power [kW]                      | 240         | 240                                                   | 170           | 170                     | 134        |

| London    | 8 (11,9 m)                 | 16-18                      | 1298565                         | 9,7                                      | 480469                 |
| Milan     | 3 (12 m)                   | 0-17                       | 178396                          | 10,3                                     | 100259                 |
| Oslo      | 5 (13,2 m)                 | 0-17                       | 546223                          | 13,2                                     | 273112                 |
| Berlin    | 4 (12 m)                   | n/a                        | 898477                          | 22,8                                     | 377360                 |
| Cologne   | 2 (18,5 m)                 | 12-16                      | 109790                          | 16,5                                     | 48813                  |
| Cologne   | 2 (13,2 m)                 | 12-16                      | 122656                          | 12,5                                     | 54533                  |
| Hamburg   | 4 (12 m)                   | 0-16                       | 457712                          | 8                                        | 171651                 |
| Whistler  | 20 (12,5 m)                | 0-22                       | >4005000                        | 15,67                                    | 2202750                |

Table 3: Statistics over the project period in the CHIC project (31)

According to the CHIC report, more than 850 buses are in planning globally (31). During the project period, from 2010-2016, the costs of hydrogen fueled buses have decreased dramatically. At the start of the project a 12-meter bus cost well over € 1 million, with expected cost in 2017 being € 650 000. It is believed this price ultimately, with technology improvements and increased sale volumes of buses and passenger cars, will go below € 400 000 (31).

Not much information is available regarding trains fueled by hydrogen, as this area is even younger than for buses. The first fuel cell passenger train, Coradia iLint, is in 2017 being extensively tested in Germany and Czech Republic (32). The Coradia iLint will run its first passenger test runs in Germany in the beginning of 2018.

*Figure 1: Alstom's hydrogen train Coradia iLint on its test track in Salzgitter, Germany (32)*

### *Heavy-duty trucks and cargo vans*

ASKO, Norway's largest wholesaler (33), aims to become climate neutral (34). As a vital step towards this goal, ASKO has placed an order for three fuel cell cargo vans fueled by hydrogen from Scania with a range of up to 500 km. ASKO plans to establish a facility for hydrogen production for fueling of these cargo vans (34). Director of ASKO, Jørn Endresen, states that the cost of these trucks amount to 7 million NOK, and that they estimate hydrogen trucks to be price competitive with traditional diesel trucks in the early 2020s (35).

Nikola Motor Company, located in Salt Lake City, have developed two models of hydrogen fueled semi-trucks (36). One with a sleeping compartment and one without. Nikola states their truck to have 1 000 horsepower, which translates to 746 kW, and a range of 800-1200 miles, which translates to roughly 1300-1900 km (37). The average hydrogen consumption is estimated to be 4.6 kg/100 km (38).

Renault have developed a hydrogen fueled truck named Renault Maxity with a range of 200 km, hydrogen fuel cell of 20 kW charging the batteries and power of the electrical motor of 47 kW (39).

E-trucks Europe deployed in 2013 their hydrogen powered garbage truck (40). This truck has a range of 360 km. The truck is reported to save 109.37 kg CO<sub>2</sub> each operational day, amounting to 4.83 tons per year (40). Equipped with a 30 kW fuel cell providing energy for the battery and a power output of 144 kW from the electrical motor, the truck has a hydrogen consumption of 6-9 kg/100 km (41).

Esoro Konsortium have developed a fuel cell truck with 375-400 km range, average hydrogen consumption of 7.5-8 kg/100 km, fuel cell of 100 kW and electrical motor power output of 250 kW (42).

An overview of the discussed manufacturers' products is listed in Table 4.

| Manufacturer     | Range [km] | Motor power [kW] | Average hydrogen consumption [kg/100 km] |
|------------------|------------|------------------|------------------------------------------|
| Scania           | <500       | n/a              | n/a                                      |
| Nikola Motor     | 1300-1900  | 746              | 4.6                                      |
| Renault Maxity   | 200        | 47               | n/a                                      |
| E-trucks Europe  | 360        | 144              | 6-9                                      |
| Esoro Konsortium | 375-400    | 250              | 7.5-8                                    |

Table 4: Overview of hydrogen trucks (34, 38, 41-44)

### 2.2.5 Metal industry

In Tysedal, Norway, TiZir Titanium & Iron (TTI) are planning to replace the use of coal in their production line and begin using hydrogen instead in order to reduce their greenhouse gas emissions by 90 % (45).

Today, TTI's process involves partial oxidation of the ilmenite ore (FeTiO<sub>3</sub>) in a rotary kiln at 1 100 °C together with coal, where 70-75 % of the iron is prereduced to metal (46). The remaining ilmenite is then fed into an electric arc furnace, reducing the rest of the iron.

The simplified chemical reaction equations occurring in the process is given in Equation 23 and Equation 24.

Equation 23: Carbon in the coal reacts to form carbon monoxide (46)

Equation 24: Ilmenite reacts with carbon monoxide to form iron, titanium dioxide and carbon dioxide (46)

As can be seen from Equation 23, carbon in the coal is oxidized by carbon dioxide to form carbon monoxide. It is this carbon monoxide which in turn acts as the reducing agent in Equation 24.

Lobo (46) states that hydrogen increases reaction rate compared to the present process, with the increased reaction rate being proportional to the volume percentage of hydrogen in the gas.

## 2.3 Distribution of hydrogen

The favorable options for distribution of hydrogen are suggested to be the utilization of heavy-duty vehicles for national transportation and shipping for international transportation (47). In the former hydrogen would be transported as compressed hydrogen gas, while in the latter hydrogen would be transported as liquid hydrogen (47).

### 2.3.1 Shipping

Kamiya et al. have estimated hydrogen costs for a system where hydrogen is produced by the use of brown coal in Australia, liquefied and transported by ship to Japan (48). Here, CO<sub>2</sub> is assumed to be stored through the CarbonNet Project, which utilizes the offshore storage sites in Gippsland (49). Kamiya et al. estimate liquefaction, transportation by ship and CO<sub>2</sub> storage to amount to respectively 33 %, 9 % and 10 % of the total costs of hydrogen (48). With the price of hydrogen being estimated to be \$ 3.23/kg H<sub>2</sub>, liquefaction, transportation by ship and CO<sub>2</sub> storage amount to respectively \$ 1.07/kg H<sub>2</sub>, \$ 0.29/kg H<sub>2</sub> and \$ 0.32/kg H<sub>2</sub> (48).

### 2.3.2 Heavy-duty vehicles

Through one of their projects, Greenstat have come to an estimate of 56 NOK/km for transportation of high pressure hydrogen (50). This estimate is used as a basis for calculations on distribution of hydrogen in this report. However, this cost of 56 NOK/km does not include capital investment in the actual containers (50). As such, the actual cost per kilometer depends on how frequently these containers are used. Greenstat consider 40 feet containers with a storage pressure of 300 bar to be most beneficial for their use, and list the following container suppliers as good alternatives:

- Hexagon: 845 kg H<sub>2</sub>/container at 4.715 MNOK
- Wystrach: 900 kg H<sub>2</sub>/container at 5.280 MNOK
- Umoe: 785 kg H<sub>2</sub>/container at 2.570 MNOK

## 2.4 Carbon capture and storage

Storage of CO<sub>2</sub> today mostly happens due to injection of CO<sub>2</sub> into oil wells to improve recovery of oil (EOR). The majority of these projects use CO<sub>2</sub> from natural geologic accumulations. Some use anthropogenic CO<sub>2</sub>, but only a few of these perform a sufficient degree of monitoring, measurement

and verification (MMV) to qualify as CCS. As such, they cannot determine whether storage of CO<sub>2</sub> is likely to be permanent (51). Haugan argues that the research necessary to determine whether storage of CO<sub>2</sub> in a specific storage location is likely to be permanent or not is costly and time consuming, and that such locations should not be used for storage of CO<sub>2</sub> if that CO<sub>2</sub> may be removed by other measures (52).

Atkins Norge and Oslo Economics have carried out socioeconomic analyses of CCS alternatives in Norway (53).

They estimate that an 8-year period is required for concept studies and investment phases, before operation can begin in the ninth year of a CCS project (53). Seven potential projects have been analyzed, which are compared with each other and two additional projects. An overview of the costs per ton CO<sub>2</sub> for the various projects is presented in Table 5.

| Project name                | Abatement cost [NOK/ton CO <sub>2</sub> ] |
|-----------------------------|-------------------------------------------|
| CCS White Rose (UK gov)     | 1650                                      |
| CCS Peterhead (UK gov)      | 4850                                      |
| CCS Mongstad                | 2900                                      |
| CCS three sources           | 1400                                      |
| CCS cement and small source | 1650                                      |
| CCS waste                   | 2400                                      |
| CCS ammonia                 | 1700                                      |
| CCS cement                  | 2250                                      |
| CCS minimum                 | 2900                                      |

Table 5: Abatement cost of emission reductions via CCS (53)

Atkins Norge and Oslo Economics conclude that with today’s market pricing of CO<sub>2</sub>, an investment in CCS is not socioeconomically advantageous (53).

Knoope et al. have analyzed the net present value (NPV) of investments into CCS infrastructure solutions (54). Two alternative infrastructure solutions are analyzed: transportation of CO<sub>2</sub> by ship and by pipeline. Overviews of the economic estimates made by Knoope et al. are presented in Table 6 and Table 7.

| CCS with pipeline solution                                        |                            |        |                              |        |                                                                  |        |
|-------------------------------------------------------------------|----------------------------|--------|------------------------------|--------|------------------------------------------------------------------|--------|
|                                                                   | 1 Mt CO <sub>2</sub> /year |        | 2.5 Mt CO <sub>2</sub> /year |        | 10 Mt CO <sub>2</sub> /year (fixed project duration of 25 years) |        |
|                                                                   | 250 km                     | 500 km | 250 km                       | 500 km | 250 km                                                           | 500 km |
| NPV whole CCS project (MNOK)                                      | -2854                      | -4029  | -2588                        | -4532  | 3157                                                             | -542   |
| Overall levelized costs (NOK/ton CO <sub>2</sub> )                | 711                        | 865    | 474                          | 575    | 298                                                              | 346    |
| Required initial CO <sub>2</sub> price (NOK/ton CO <sub>2</sub> ) | 696                        | 847    | 464                          | 563    | 291                                                              | 338    |

Table 6: Net present value estimates of CCS with pipeline solution (54)

As can be seen in Table 6, various pipeline capacities are analyzed, along with two different distances of transportation; 250 km and 500 km. The authors also analyzed a pipeline with capacity of 10 Mt CO<sub>2</sub>/year and limited storage capacity. This is not included because many of the CO<sub>2</sub> storage locations on Norwegian territory have storage capacities far exceeding 250 Mt CO<sub>2</sub> (55-57). Of the three areas the Barents Sea, the Norwegian Sea and the Norwegian North Sea, the Barents Sea and the Norwegian Sea have at least one storage location with sufficient capacity (56, 57). The Norwegian North Sea has several locations with capacities of the gigaton class (55). From Table 6, one can see that only storage of 10 Mt CO<sub>2</sub>/year at a distance of 250 km yields a positive net present value, and that with an initial CO<sub>2</sub> price of 291 NOK/ton CO<sub>2</sub>. Note that the CO<sub>2</sub>-price in the report of Knoope et al. is set to increase by 3 % per year (54).

| CCS with ship solution                                            |                            |        |                              |        |                                                                  |        |
|-------------------------------------------------------------------|----------------------------|--------|------------------------------|--------|------------------------------------------------------------------|--------|
|                                                                   | 1 Mt CO <sub>2</sub> /year |        | 2.5 Mt CO <sub>2</sub> /year |        | 10 Mt CO <sub>2</sub> /year (fixed project duration of 25 years) |        |
|                                                                   | 250 km                     | 500 km | 250 km                       | 500 km | 250 km                                                           | 500 km |
| NPV whole CCS project (MNOK)                                      | -2607                      | -2664  | -2654                        | -2787  | -12                                                              | -881   |
| Overall levelized costs (NOK/ton CO <sub>2</sub> )                | 679                        | 686    | 478                          | 484    | 339                                                              | 351    |
| Required initial CO <sub>2</sub> price (NOK/ton CO <sub>2</sub> ) | 665                        | 672    | 467                          | 474    | 332                                                              | 347    |

Table 7: Net present value estimates of CCS with ship solution (62)

As can be seen in Table 7, various ship capacities are analyzed, along with two different distances of transportation; 250 km and 500 km. The authors also analyzed a ship with capacity of 10 Mt CO<sub>2</sub>/year and limited storage capacity. This is not included because many of the CO<sub>2</sub> storage locations on Norwegian territory have storage capacities far exceeding 250 Mt CO<sub>2</sub> (55-57). None of the proposed solutions yield a positive net present value.

## 2.5 Environmental impact

Hydrogen is, as of 2016, produced mainly from natural gas steam reforming without CCS, accounting for 48 % of all hydrogen production. The remainder comes from petroleum production during the refining process accounting for 30 %, coal based hydrogen represents 18 % and the rest, 4 %, is hydrogen produced with electrolysis (8). The production of this hydrogen resulted in approximately 500 million tons CO<sub>2</sub>-equivalents worth of emissions (8).

According to Dincer and Acar (13), hydrogen production by water electrolysis has a GWP of 8 kg CO<sub>2</sub>-equivalents/kg H<sub>2</sub> produced. It is not stated which energy source this electrolysis is based upon. They cite their results by basing the environmental impact numbers on Ozbilen et al (58) and Bhandari et al. (59).

According to Ozbilin et al. (58), solar based electrolysis results in approximately 2.4 kg CO<sub>2</sub>-equivalents/kg H<sub>2</sub> production, considerably more than wind based electrolysis of about 0.6 kg CO<sub>2</sub>-equivalents/kg H<sub>2</sub> production. Steam methane reforming accounts for roughly 11.7 kg CO<sub>2</sub>-equivalents/kg H<sub>2</sub> production. This report was published in 2013. However, the calculations for solar, wind and SMR hydrogen production stem from reports of respectively 2004 (60), 2004 (61) and 2001 (62).

Bhandari et al. (59) report GWP of solar based electrolysis to range from approximately 2-8 kg CO<sub>2</sub>-equivalents/kg H<sub>2</sub> produced. Hydro, wind and solar thermal electrolysis are reported to have a GWP from roughly 0.6-3 kg CO<sub>2</sub>-equivalents/kg H<sub>2</sub> produced. Electrolysis with electricity fed from the power grid is reported to have a GWP of 31-32 kg CO<sub>2</sub>-equivalents/kg H<sub>2</sub> produced. The latter has an enormous GWP due to a high share of fossil fuel resources in the grid electricity mix. The wider spread of values from Bhandari et al. is due to their report being based on a significantly larger number of sources, ranging from being published in 2001 to 2012.

### 2.5.1 Social costs of carbon

The relation social costs of carbon (SCC), expressed as social costs per ton CO<sub>2</sub> released, is the linking of damage due to emissions of GHGs causing changing climate with CO<sub>2</sub> emissions (63).

In a report published by the International Panel on Climate Change, an SCC of \$ 90/t CO<sub>2</sub> is presented as the best estimate (63). These are 2005 USD. Their range of estimates is converted to 2017 NOK and presented in Table 8 (63).

| Greenhouse gas    | Minimum social cost (NOK/kg) | Best guess social cost (NOK/kg) | Maximum social cost (NOK/kg) |
|-------------------|------------------------------|---------------------------------|------------------------------|
| CO <sub>2</sub>   | 0,182                        | 0,964                           | 3,748                        |
| CH <sub>4</sub>   | -                            | -                               | -                            |
| N <sub>2</sub> O  | -                            | -                               | -                            |
| SO <sub>2</sub>   | 42,834                       | -                               | 107,084                      |
| NO <sub>x</sub>   | 21,417                       | -                               | 107,084                      |
| nmVOC             | -                            | -                               | -                            |
| NH <sub>3</sub>   | -                            | -                               | -                            |
| PM <sub>2,5</sub> | 107,084                      | -                               | 7535,000                     |

Table 8: Social costs of various greenhouse gases as reported by the IPCC (63)

In a report published by the climate and pollution agency both social costs of CO<sub>2</sub> and abatement costs were estimated (64). Their range of estimates is presented in Table 9 (64).

| Greenhouse gas   | Minimum abatement cost (NOK/kg) | Maximum abatement cost (NOK/kg) | Minimum social cost (NOK/kg) | Maximum social cost (NOK/kg) |
|------------------|---------------------------------|---------------------------------|------------------------------|------------------------------|
| CO <sub>2</sub>  | 0,255                           | -                               | -                            | -                            |
| CH <sub>4</sub>  | 5,364                           | -                               | -                            | -                            |
| N <sub>2</sub> O | 79,183                          | -                               | -                            | -                            |
| SO <sub>2</sub>  | 15                              | 23                              | 19                           | 166                          |
| NO <sub>x</sub>  | 26                              | 38                              | 32                           | 153                          |
| nmVOC            | 1                               | 2                               | -                            | -                            |
| NH <sub>3</sub>  | -                               | -                               | 0                            | 8                            |
| PM10             | -                               | -                               | 255                          | 7 535                        |

*Table 9: Abatement and social costs of various greenhouse gases as reported by the Norwegian climate and pollution agency (64)*

## 2.6 National forecast

Emissions within Norwegian territory in 2015 amounted to 53.9 million tons CO<sub>2</sub>-equivalents (5). The main contributors are oil and gas extraction with 15.1 million tons, industry and quarrying with 11.9 million tons and road traffic with 10.3 million tons. Most of the emissions from oil and gas extraction and industry and quarrying are subject to the quotas trading system (65). Accumulated emissions subject to the quotas trading system in 2015 amounted to 27.9 million tons CO<sub>2</sub>-equivalents (5).

Norway has committed to reducing the national emissions by at least 40 % by 2030 with respect to the emission level of 1990 (66). National emissions of 1990 amounted to 51.73 million tons CO<sub>2</sub>-equivalents (5). By this, national emissions must be reduced by 22.86 million tons CO<sub>2</sub>-equivalents in the period 2015-2030. In order to meet national targets, the Norwegian government takes aim to achieve a set of goals, some of which are listed in the following (67):

1. By 2025, all new passenger vehicles and cargo vans shall be zero-emission vehicles.
2. By 2025, all new city buses shall be zero-emission vehicles or run on biogas.
3. By 2030, all new heavy-duty vehicles, 75 % of all new long-distance buses and 50 % of all new trucks shall be zero-emission vehicles.
4. Ensure that all vehicle ferries utilize low or zero-emission solutions and contribute to ferries on county level and express boats utilize low or zero-emission solutions.

The Institute of Transport Economics presented in December 2016 a report where two scenarios for the Norwegian emission development toward 2050 are highlighted (68). In scenario one,

“Trendbanen” translating to the trend path, current developments in the national car stock are prolonged. If this scenario comes true, CO<sub>2</sub> emissions from road traffic will decrease by 21 % from 2015 to 2030 (68). In 2015, national emissions amounted to 10.3 million tons CO<sub>2</sub>-equivalents (5). By 2030 this will then amount to 8.14 million tons CO<sub>2</sub>-equivalents, which is still more than 1990-levels of 7.77 million tons CO<sub>2</sub>-equivalents.

Scenario two, “Ultralavutslippsbanen” translating to the ultra-low emission policy scenario, is tailored towards achieving the suggested goals set by the Norwegian transport agencies (69). These goals are in essence the same as those the Norwegian government takes aim to achieve (67). However, the Norwegian transport agencies do not allow new city buses to run on biogas as listed in point 2 above.

Nonetheless, the estimates by the Institute of Transport Economics give an impression of what the development in the transport sector might look like in the long term transition to a zero-emission transport sector (68):

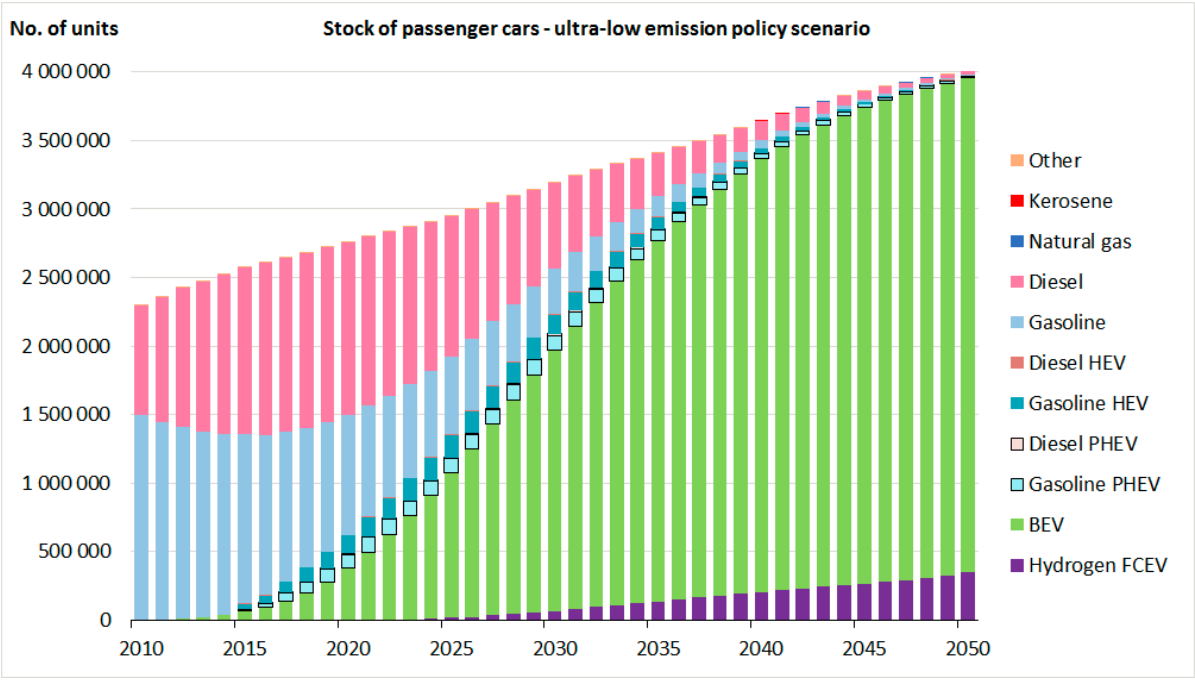

Figure 2: Composition of the Norwegian passenger vehicle stock from 2010-2050 in the ultra-low emission scenario (68).

Figure reused with permission.

Figure 2 shows potential development of the Norwegian stock of passenger cars in the ultra-low emission policy scenario. In this scenario, battery electric vehicles dominate the stock of passenger cars towards 2050, taking over from diesel and gasoline.

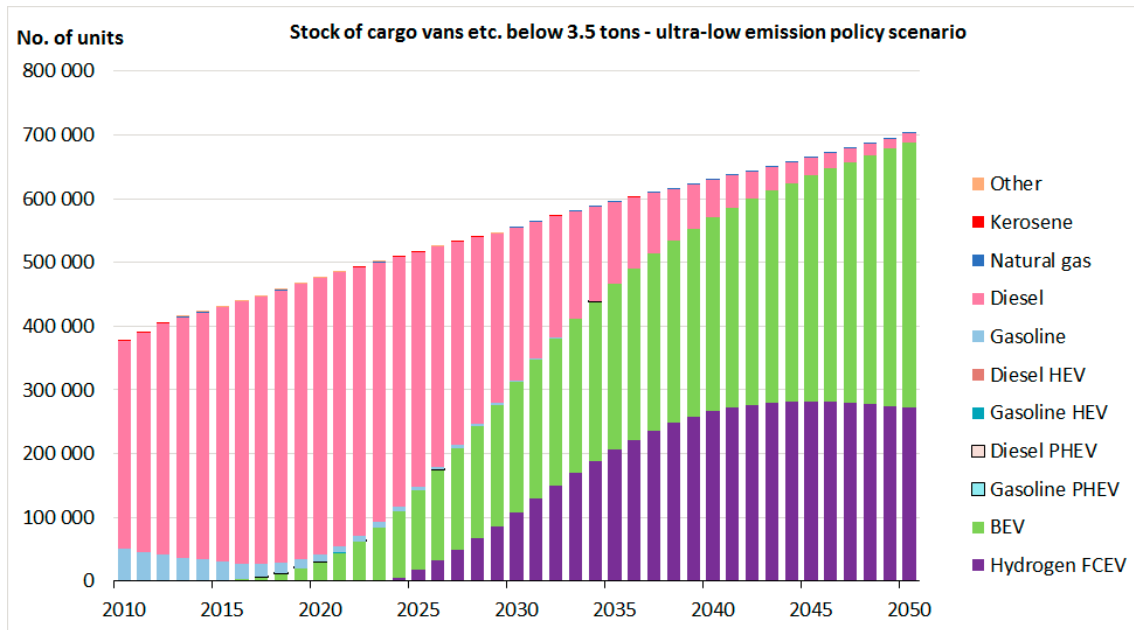

Figure 3: Composition of the Norwegian cargo van stock from 2010-2050 in the ultra-low emission scenario (68). Figure reused with permission.

Figure 3 displays potential development of the Norwegian stock of cargo vans in the ultra-low emission policy scenario. Here the stock is dominated by diesel vehicles, and is gradually substituted by battery electric vehicles and hydrogen fuel cell electric vehicles.

Figure 4: Composition of the Norwegian heavy-duty trucks and tractor units stock from 2010-2050 in the ultra-low emission scenario (68). Figure reused with permission.

As can be seen in Figure 4, the stock of heavy-duty trucks and tractor units in this scenario transitions mainly from diesel vehicles to hydrogen FCEVs.

Figure 5: Composition of the Norwegian bus stock from 2010-2050 in the ultra-low emission scenario (68). Figure reused with permission.

In Figure 5, development of the Norwegian stock of buses in the ultra-low emission scenario is shown. Here, diesel vehicles presently have the majority share, while BEVs and hydrogen FCEVs gradually take over.

Based on the calculations made by the Institute of Transport Economics, it is clear that in the transition towards a zero-emission society, battery electric vehicles will be dominating in the passenger car and cargo van stocks, while hydrogen fuel cell electric vehicles will be dominating in the heavy-duty trucks and tractor units and bus stocks.

### 3 Economic analyses

In the following, economic analyses of hydrogen production methods and usage of hydrogen in the transport sector will be presented and the potential GHG reductions and their respective costs will be discussed in light of Norway's climate goals.

#### 3.1 Hydrogen production methods

In this chapter, costs of hydrogen production methods discussed in chapter 2.1 are presented.

##### 3.1.1 Steam-methane reforming method

A study performed by Bartels et al. (70) presents a hydrogen cost relationship developed by Gray and Tomlinson (71) as follows

$$C_{\text{H}_2, \text{G\&T}} \left( \frac{\$}{\text{MMBtu}} \right) = 1.27 \cdot \text{NG price} \left( \frac{\$}{\text{MMBtu}} \right) + 0.985$$

*Equation 25: Relationship for cost of hydrogen (71)*

Equation 25 is applicable to facilities with a production rate of around 100 million standard cubic feet per day (SCFD). This equals 236 239 kg/day. These facilities shall also have a capital cost of \$ 0.65-0.8/SCFD and a thermal efficiency of 70 % or higher based on natural gas' higher heating value. With this, Bartels et al. estimated the hydrogen cost to be \$ 2.48/kg in 2007 dollars. Their calculation is based on a price of natural gas of \$ 10.00/MMBtu from April 2008. Adjusted to 2017 dollars this becomes

$$\begin{aligned} C_{\text{H}_2, \text{G\&T}} \left( \frac{\$}{\text{kg}} \right) &= \frac{\text{CPI in January 2017}}{\text{Annual average CPI 2007}} \cdot \text{Hydrogen cost 2007} \\ &= \frac{242.839}{207.342} \cdot 2.48 \frac{\$}{\text{kg}} = 2.905 \frac{\$}{\text{kg}} \end{aligned}$$

*Equation 26: hydrogen cost by the Consumer Price Index inflation formula*

Which in 2017 NOK becomes 24.39 NOK/kg H<sub>2</sub>.

Consumer Price Indices (CPI) for 2007 and 2017 are collected from the Bureau of Labor Statistics (72). The 2007 average CPI is taken from the report "Annual Average Indexes 2007 (Tables 1A-23A)" in table 1A, for *all items*. The 2017 January CPI is collected from report "January 2017 (complete text and tables)" in table 1, for *all items*.

Penner (73) has given a similar hydrogen cost equation as follows

$$C_{\text{H}_2, \text{Penner}} \left( \frac{\$}{\text{kg}} \right) = 0.286 \cdot \text{NG price} \frac{\$}{\text{MMBtu}} + 0.15$$

Equation 27: Penner's equation for hydrogen cost (73)

According to the U.S. Energy Information Administration (74), the December 2016 natural gas price was 4.32 \$/Mcf (Dollars per 1,000 cubic feet (75)). Converted to MMBtu this becomes

$$\text{NG price} \frac{\$}{\text{MMBtu}} = 4.32 \frac{\$}{\text{Mcf}} \cdot \frac{1 \text{ Mcf}}{1.032 \text{ MMBtu}} = 4.186 \frac{\$}{\text{MMBtu}}$$

Equation 28: Natural gas price conversion from \$/Mcf to \$/MMBtu

With this, the hydrogen cost is

$$C_{\text{H}_2, \text{Penner}} \left( \frac{\$}{\text{kg}} \right) = 0.286 \cdot 4.186 \frac{\$}{\text{MMBtu}} + 0.15 = 1.347 \frac{\$}{\text{kg}}$$

Equation 29: Penner's hydrogen cost equation solved for January 2017 natural gas price

Which in 2017 NOK becomes 11.31 NOK/kg H<sub>2</sub>.

Since the hydrogen cost from Equation 26 is based on a cost of natural gas of \$ 10/MMBtu from April 2008, it is worth attempting to convert this into a price for hydrogen based on natural gas for 2017, as is done with Penner's formula.

Bartels et al. estimate a price of \$ 2.48/kg H<sub>2</sub> when adjusted to 2007 dollars and converted from \$/MMBtu to \$/kg H<sub>2</sub>. This means there are two variables to consider when using a new price for natural gas. In Penner's formula only the adjustment to 2007 dollars is performed, meaning this adjustment factor can be found by the following

$$\begin{aligned} \text{Adjustment factor} &= \frac{3.17 \frac{\$}{\text{kg}}}{\left( 0.286 \cdot \text{NG price} \frac{\$}{\text{MMBtu}} + 0.15 \right) \frac{\$}{\text{kg}}} \\ &= \frac{3.17 \frac{\$}{\text{kg}}}{\left( 0.286 \cdot 10.00 \frac{\$}{\text{MMBtu}} + 0.15 \right) \frac{\$}{\text{kg}}} = \underline{1.053} \end{aligned}$$

Equation 30: Adjustment factor to 2007 dollars

Assuming the two calculations use the same adjustment factor, the conversion factor from \$/MMBtu to \$/kg H<sub>2</sub> can now be found.

$$\text{Conversion factor} = \frac{\left(1.27 \cdot \text{NG price} \frac{\$}{\text{MMBtu}} + 0.985\right) \frac{\$}{\text{kg}}}{\frac{2.48 \frac{\$}{\text{kg}}}{1.053}} = 5.811$$

*Equation 31: Factor for conversion from \$/MMBtu to \$/kg hydrogen*

As such, the January 2017 industrial natural gas price can be applied to the modified Equation 25, including the conversion factor calculated with Equation 31

$$\begin{aligned} C_{\text{H}_2, \text{G\&T}} \left( \frac{\$}{\text{kg}} \right) &= \frac{1.27 \cdot \text{NG price} \left( \frac{\$}{\text{MMBtu}} \right) + 0.985}{\text{Conversion factor}} \\ &= \frac{1.27 \cdot 4.186 \left( \frac{\$}{\text{MMBtu}} \right) + 0.985}{5.811} = \underline{\underline{1.084 \frac{\$}{\text{kg}}}} \end{aligned}$$

*Equation 32: Gray and Tomlinson's hydrogen cost equation solved with January 2017 natural gas price*

This gives 9.1 NOK/kg H<sub>2</sub> in 2017 NOK.

Bartels et al. (70) also discuss two more hydrogen production plants studied by Rutkowski (76), one with carbon capture technology and one without. These plants have a production capacity of 379 387 kg H<sub>2</sub>/day and production output of 341 448 kg H<sub>2</sub>/day at 90 % capacity factor. Bartels et al. adjusted their estimated hydrogen costs to \$ 2.55/kg H<sub>2</sub> and \$ 2.33/kg H<sub>2</sub> for steam methane reforming, with and without CCS, respectively (70). This is done with the same natural gas price as previously at \$ 10.00/MMBtu from April 2008 and adjustment to 2007 dollars. By adjusting for the

difference in natural gas price of April 2008 and December 2016 and for inflation between 2007 and January 2017, the hydrogen cost can be estimated for January 2017 prices

$$C_{H_2, \text{Rutkowski}_{\text{CCS}}} \left( \frac{2017 \$}{\text{kg}} \right) = 2.55 \frac{2007 \$}{\text{kg}} \cdot \frac{\text{December 2016 NG price} \frac{\$}{\text{MMBtu}}}{\text{April 2008 NG price} \frac{\$}{\text{MMBtu}}} \cdot \frac{\text{CPI in January 2017}}{\text{Annual average CPI 2007}}$$

$$= 2.55 \frac{\$}{\text{kg}} \cdot \frac{4.186 \frac{\$}{\text{MMBtu}}}{10.00 \frac{\$}{\text{MMBtu}}} \cdot \frac{242.839}{207.342} = 1.250 \frac{2017 \$}{\text{kg}}$$

*Equation 33: hydrogen cost with CCS based on Rutkowski (70) and adjusted to December 2016 industrial natural gas price and January 2017 Consumer Price Index*

This gives 10.5 NOK/kg H<sub>2</sub> in 2017 NOK.

$$C_{H_2, \text{Rutkowski}_{\text{Non-CCS}}} \left( \frac{2017 \$}{\text{kg}} \right) = 2.33 \frac{2007 \$}{\text{kg}} \cdot \frac{\text{January 2017 NG price} \frac{\$}{\text{MMBtu}}}{\text{April 2008 NG price} \frac{\$}{\text{MMBtu}}} \cdot \frac{\text{CPI in January 2017}}{\text{Annual average CPI 2007}}$$

$$= 2.33 \frac{\$}{\text{kg}} \cdot \frac{4.186 \frac{\$}{\text{MMBtu}}}{10.00 \frac{\$}{\text{MMBtu}}} \cdot \frac{242.839}{207.342} = 1.142 \frac{2017 \$}{\text{kg}}$$

*Equation 34: hydrogen cost without CCS based on Rutkowski (70) and adjusted to December 2016 industrial natural gas price and January 2017 Consumer Price Index*

This gives 9.59 NOK/kg H<sub>2</sub> in 2017 NOK.

### 3.1.2 Biomass

Padró and Putsche (77) found hydrogen costs from biomass gasification to range from \$ 8.69/GJ H<sub>2</sub> produced to \$ 17.1/GJ H<sub>2</sub> produced using lower heating value, depending on production plant size. Based on the lower and higher heating value of hydrogen, respectively 120.0 MJ/kg and 141.8 MJ/kg (37), and accounting for inflation, the cost of hydrogen in 2017 dollars becomes

$$C_{H_2, \text{P\&P, LHV, low}} \left( \frac{\$}{\text{kg}} \right) = \frac{\text{CPI in January 2017}}{\text{Annual average CPI 1999}} \cdot C_{H_2, \text{low, 1999}} \cdot \text{LHV}_{H_2}$$

$$= \frac{242.839}{166.6} \cdot 8.69 \frac{\$}{\text{GJ}} \cdot 0.12 \frac{\text{GJ}}{\text{kg}} = 1.52 \frac{\$}{\text{kg}}$$

*Equation 35: Lower cost of hydrogen from Padró and Putsche (77) when accounting for inflation and lower heating value*

This gives 12.76 NOK/kg H<sub>2</sub> in 2017 NOK.

$$C_{H_2, P\&P, LHV, high} \left( \frac{\$}{kg} \right) = \frac{\text{CPI in January 2017}}{\text{Annual average CPI 1999}} \cdot C_{H_2, high, 1999} \cdot LHV_{H_2}$$

$$= \frac{242.839}{166.6} \cdot 17.1 \frac{\$}{GJ} \cdot 0.12 \frac{GJ}{kg} = 2.99 \frac{\$}{kg}$$

Equation 36: Higher cost of hydrogen from Padró and Putsche (77) when accounting for inflation and lower heating value

This gives 25.11 NOK/kg H<sub>2</sub> in 2017 NOK.

$$C_{H_2, P\&P, HHV, low} \left( \frac{\$}{kg} \right) = \frac{\text{CPI in January 2017}}{\text{Annual average CPI 1999}} \cdot C_{H_2, low, 1999} \cdot HHV_{H_2}$$

$$= \frac{242.839}{166.6} \cdot 8.69 \frac{\$}{GJ} \cdot 0.1418 \frac{GJ}{kg} = 1.80 \frac{\$}{kg}$$

Equation 37: Lower cost of hydrogen from Padró and Putsche (77) when accounting for inflation and higher heating value

This gives 15.12 NOK/kg H<sub>2</sub> in 2017 NOK.

$$C_{H_2, P\&P, HHV, high} \left( \frac{\$}{kg} \right) = \frac{\text{CPI in January 2017}}{\text{Annual average CPI 1999}} \cdot C_{H_2, high, 1999} \cdot HHV_{H_2}$$

$$= \frac{242.839}{166.6} \cdot 17.1 \frac{\$}{GJ} \cdot 0.1418 \frac{GJ}{kg} = 3.53 \frac{\$}{kg}$$

Equation 38: Higher cost of hydrogen from Padró and Putsche (77) when accounting for inflation and higher heating value

This gives 29.64 NOK/kg H<sub>2</sub> in 2017 NOK.

Consumer Price Indices (CPI) for 1999 and 2017 are collected from the Bureau of Labor Statistics (72). The 1999 average CPI is taken from the report “Annual Average Indexes 2000 (Tables 1A-23A)” in table 1A, for *all items*. The 2017 January CPI is collected from report “January 2017 (complete text and tables)” in table 1, for *all items*.

### 3.1.3 Partial oxidation method

Using coal as a feedstock, Bartels et al. (70) have reviewed several studies done on hydrogen production facilities. The common denominator of these facilities is that they all produce electricity to one extent or another, decreasing the resulting cost of hydrogen. Assuming this electricity can be sold to utility companies or to an industrial user of hydrogen for a comparable price to what it is assumed to be sold for in Gray and Tomlinson’s study (71), the relevance of the electricity produced can be neglected. Additionally, these facilities produce hydrogen in a range of 281 100-770 700 kg H<sub>2</sub>/day. Lastly, the carbon sequestration ranges from 0-100 %, where 0 % means less costly hydrogen and vice versa. Bartels et al. report a hydrogen cost of \$ 1.63/kg H<sub>2</sub> for a plant including CCS and a hydrogen

production rate of 276 900 kg H<sub>2</sub>/day and \$ 1.34/kg H<sub>2</sub> for a plant without CCS and a hydrogen production rate of 255 400 kg H<sub>2</sub>/day. Which in NOK becomes 13.69 and 11.25 NOK/kg H<sub>2</sub>, respectively.

#### 3.1.4 Autothermal reforming method

Nikolaidis et al. (10) claim the optimum operating temperature for ATR hydrogen production from methane to be 700 °C. Additionally, they state the ATR investment costs to be 15-25 % lower than those of SMR. Hydrogen production from advanced large-scale ATR plants with a CO<sub>2</sub> capture and storage of 90 % and investment costs at about \$ 500/kW, would enable a price of \$ 1.48/kg H<sub>2</sub> gas produced. Which in NOK becomes 12.43 NOK/kg H<sub>2</sub>.

#### 3.1.5 Water electrolysis

Gray and Tomlinson have estimated costs of hydrogen from photovoltaic electrolysis varying from 0.98 to \$ 6.02/kg H<sub>2</sub>. This is in 2007 dollars. Utilizing Equation 26 and converting to NOK, this becomes 9.64 to 59.21 NOK/kg H<sub>2</sub>.

### 3.1.6 Summary

In this section, a summary of the costs of the hydrogen production technologies found in the literature is presented via Table 10 (10, 70, 71, 73, 76, 77).

| Costs of hydrogen production technologies |                    |                                   |     |                                  |
|-------------------------------------------|--------------------|-----------------------------------|-----|----------------------------------|
|                                           | Source             | Scale<br>[kg H <sub>2</sub> /day] | CCS | Cost<br>[NOK/kg H <sub>2</sub> ] |
| SMR                                       | Gray and Tomlinson | 236 239                           | NA  | 9,1                              |
|                                           | Penner             | NA                                | NA  | 11,31                            |
|                                           | Rutkowski          | 379 387                           | Yes | 10,5                             |
|                                           | Rutkowski          | 341 448                           | No  | 9,59                             |
| POX                                       | Bartels et al.     | 276 900                           | Yes | 13,69                            |
|                                           | Bartels et al.     | 255 400                           | No  | 11,25                            |
| ATR                                       | Nikolaidis et al.  | NA                                | Yes | 12,43                            |
| Hydrocarbon pyrolysis                     | -                  | -                                 | -   | -                                |
| Thermochemical, biomass                   | Padró & Putsche    | 197 736                           | NA  | 12,76-15,12                      |
|                                           | Padró & Putsche    | 1977                              | NA  | 25,11-29,64                      |
| Biological, biomass                       | -                  | -                                 | -   | -                                |
| Water electrolysis                        | Gray and Tomlinson | NA                                | -   | 9,64-59,21                       |
| Water thermolysis                         | -                  | -                                 | -   | -                                |

Table 10: Costs of hydrogen production technologies, brief literature review

## 3.2 The TiZir case

In this chapter, the aim is to provide TiZir with more information on the most relevant hydrogen production technologies (78), to the end that they may decide upon a solution for their transition with a broader understanding of the long term implications of their choice.

None of the sources found on costs of hydrogen production shown in Table 10 are of the production scale relevant for the TiZir case. As such, the relevance of scaling to costs of hydrogen must be taken into account.

As hydrogen today mainly is produced by steam methane reforming and the main competitor is water electrolysis (78), these two are the technologies of focus in this study.

### 3.2.1 Steam-methane reforming vs electrolysis

Through talks with TiZir employee Stian Seim, a list of the most relevant information on SMR and electrolysis was developed:

SMR:

- What will the price of hydrogen be?
- When will infrastructure for CCS be available?
- How will the price of emission of CO<sub>2</sub> develop due to increased CO<sub>2</sub>-tax and what consequences will that have for TiZir?
- When can a SMR facility be ready for production?

Electrolysis:

- What will the price of hydrogen be?
- When can the facility be ready for production?

The Norwegian company Reinertsen aims for the mass production of hydrogen by steam methane reforming (79). They estimate the price of hydrogen to approach 10-15 NOK/kg H<sub>2</sub> produced (79). The production rate accompanied with this price is not given.

In their master thesis, Jakobsen and Åtland have estimated breakeven prices of hydrogen vs. production capacity (80). Their results are presented in Figure 6.

Figure 6: Breakeven price of hydrogen vs production capacity (80). Figure reused with permission.

As can be seen in Figure 6, at a production capacity of 30 tons H<sub>2</sub>/day, which is TiZir’s demand, hydrogen produced with electrolysis costs roughly € 2.1/kg H<sub>2</sub>, which is roughly 19.7 NOK/kg H<sub>2</sub>. This is significantly lower than all given SMR solutions. These calculations are made using an electricity price of 188.32 NOK/MWh and 1.6 NOK/Sm<sup>3</sup>. By this, hydrogen production facilities using SMR must be of a scale 10 times greater or more than what TiZir needs. One possibility is centralized production of hydrogen with SMR and distribution.

Greenstat AS have delivered an offer to TiZir on hydrogen production of 30 tons H<sub>2</sub>/day (81). In this offer, they propose a price of hydrogen of 22.04 NOK/kg H<sub>2</sub>. In this calculation, a constant electricity price of 260 NOK/MWh is assumed. They also state that if governmental financial support is given to the project, the price of hydrogen decreases to 19.89 NOK/kg H<sub>2</sub> with the same electricity price. Greenstat estimated potential operation of the hydrogen production facility to begin 2021, but this has been offset since then (81).

According to a report on CCS by Oslo Economics and Atkins, establishment of CCS infrastructure needs 8 years from start of project to operation (53).

For TiZir to be able to go through with their expansion, the central electricity grid must be upgraded (81). Through talks with the industry, the required upgrade is estimated to take roughly 10 years (82). As the upgrade of the central grid appears to require longer time than the other factors, there should be no solution that presents a sooner start of operation than the other.

The most uncertain factor is the development of the price of hydrogen by SMR due to development of CO<sub>2</sub>-taxes. First and foremost, for CCS to become an economically viable option on the long term, the price of CO<sub>2</sub> has to increase to a level of 500-600 NOK/ton CO<sub>2</sub> (53). The development of the ranges of CO<sub>2</sub>-price needed to limit global warming to 2 °C have been estimated by the Intergovernmental Panel on Climate Change (IPCC) and the International Center for Climate Governance (ICCG), listed in Table 11 below (53):

| Development of CO <sub>2</sub> -prices for a limited global warming [NOK/ton CO <sub>2</sub> ] |      |      |      |
|------------------------------------------------------------------------------------------------|------|------|------|
| Source                                                                                         | 2020 | 2030 | 2050 |
| IPCC low                                                                                       | 121  | 197  | 522  |
| IPCC high                                                                                      | 1846 | 3098 | 6789 |
| IPCC average                                                                                   | 452  | 798  | 2040 |
| IPCC median                                                                                    | 395  | 645  | 1573 |
| ICCG average                                                                                   | 303  | 575  | 2085 |
| ICCG median                                                                                    | 265  | 605  | 1692 |

Table 11: Development of CO<sub>2</sub>-prices when limiting global warming to 2 °C (53)

In Table 11, the notation low and high represent minimum and maximum values for the CO<sub>2</sub>-price needed to limit global warming to 2 °C. The average and median values are to be considered the values closest to reality.

Outlooks on the price of CO<sub>2</sub> based on today's prices in EU ETS are given in Table 12 (53),

| Development of CO <sub>2</sub> -prices based on status quo [NOK/ton CO <sub>2</sub> ] |      |      |      |
|---------------------------------------------------------------------------------------|------|------|------|
| Source                                                                                | 2020 | 2030 | 2050 |
| EU ETS future projections                                                             | 41   | 60   | 131  |
| Thompson Reuters linear projections                                                   | 164  | 297  | 707  |

Table 12: Development of CO<sub>2</sub>-prices based on status quo (53)

To find out what consequences this can have for TiZir, estimates for emissions must be made.

Businesses bound by the quota system must deliver an equal amount of quotas to the amount of tons CO<sub>2</sub>-equivalents they have emitted (83). This means one quota equals one ton CO<sub>2</sub>-equivalent.

TiZir have been awarded roughly 356 000 quotas each year for 2017-2020 (84). Their emissions of 2016 amounted to approximately 250 000 tons CO<sub>2</sub>-equivalents.

Hydrogen produced by SMR with CCS has potential of zero-emissions as all carbon dioxide is stored instead of released to the atmosphere. Based on estimates stating replacement of coal with hydrogen in today's production line resulting in emissions amounting to 60 000 tons CO<sub>2</sub>, which is down from 300 000 tons CO<sub>2</sub> when using coal, TiZir's emissions after expansions can be estimated.

The Norwegian Environment Agency reports that the first expansion will reduce emissions by 450 000 tons CO<sub>2</sub>, and that the last expansion will reduce emissions by 900 000 tons CO<sub>2</sub> in comparison to what would have been the case with usage of coal (85). TiZir's actual emissions after these expansions are estimated assuming linear correlation in Equation 39 and Equation 40:

$$E_{\text{TiZir, exp 1}} = \left( 60000 \cdot \frac{450000}{240000} \right) \frac{\text{tonnes CO}_2}{\text{year}} = \underline{\underline{112500 \frac{\text{tons CO}_2}{\text{year}}}}$$

Equation 39: TiZir's emissions after the first expansion when using hydrogen

$$E_{\text{TiZir, exp 2}} = \left( 60000 \cdot \frac{900000}{240000} \right) \frac{\text{tonnes CO}_2}{\text{year}} = \underline{\underline{225000 \frac{\text{tons CO}_2}{\text{year}}}}$$

Equation 40: TiZir's emissions after the second expansion when using hydrogen

The total emissions connected to TiZir's production line in these scenarios are found by also estimating emissions due to production of hydrogen.

If hydrogen is produced by the use of electrolyzers and renewable electricity, Equation 39 and Equation 40 give the total emissions connected to TiZir's production line. If hydrogen is produced by the use of steam methane reforming with CCS, this is also the case assuming the CCS solution includes no leakage of CO<sub>2</sub> and that all CO<sub>2</sub> from SMR is captured.

If hydrogen is produced by the use of SMR without CCS, these emissions must also be calculated.

Chen et al. have estimated moles CO<sub>2</sub>-emissions per mole H<sub>2</sub> produced from steam methane reforming to be approximately 0.45 mol CO<sub>2</sub>/mol H<sub>2</sub> produced (86). Converted to kg CO<sub>2</sub>/kg H<sub>2</sub> this becomes:

$$\frac{m_{\text{CO}_2}}{m_{\text{H}_2}} = \frac{n_{\text{CO}_2} \cdot M_{\text{CO}_2}}{n_{\text{H}_2} \cdot M_{\text{H}_2}} = \frac{0.45 \text{ mol CO}_2 \cdot 44.009 \frac{\text{g CO}_2}{\text{mol CO}_2}}{1 \text{ mol H}_2 \cdot 2.016 \frac{\text{g H}_2}{\text{mol H}_2}} = 9.823 \frac{\text{kg CO}_2}{\text{kg H}_2}$$

Equation 41: Emitted CO<sub>2</sub> related to H<sub>2</sub> in SMR as estimated by Chen et al. (86)

With a daily production of 30 tons H<sub>2</sub>/day, the annual CO<sub>2</sub>-emissions are given by

$$m_{\text{CO}_2, \text{emissions}} = 9.823 \frac{\text{kg CO}_2}{\text{kg H}_2} \cdot 30000 \frac{\text{kg H}_2}{\text{day}} \cdot 365 \frac{\text{days}}{\text{year}} = 107\,560 \frac{\text{tonnes CO}_2}{\text{year}}$$

Equation 42: Annual CO<sub>2</sub>-emissions without CCS

Assuming 30 tons H<sub>2</sub>/day will cover today's production line, expansions 1 and 2 will cause emissions of 201.68 Mtons CO<sub>2</sub>/year and 403.35 Mtons CO<sub>2</sub>/year, respectively.

Some uncertainty exists among the industry when it comes to how much of CO<sub>2</sub>-emissions CCS solutions are able to capture. Due to a high share of nitrogen in the exhaust gases, capture of CO<sub>2</sub> appears to be limited to 90 % where SMR is concerned (87). In addition to this, Gassnova estimates leakage of CO<sub>2</sub> connected to CCS to be less than 0.0001 % of injected amount. This would increase expected costs, but it is neglected due to this amount being very small.

The potential costs due to CO<sub>2</sub>-emissions are given in Table 13 . TiZir's 356 000 quotas are assumed to be constant.

| Costs of CO <sub>2</sub> -emissions [MNOK] |      |                         |        |             |        |             |        |

| CCS economically viable                    | -    | 38,9                    | 92,2   | 73,0        | 172,8  | 145,9       | 345,6  |

Table 13: Costs of CO<sub>2</sub>-emissions in TiZir's production line

As can be seen, CO<sub>2</sub>-emissions can become very costly due to increased CO<sub>2</sub>-taxation. Depending on which development occurs, the costs with today's production line and CCS vary from 9.3 MNOK to 480.4 MNOK.

### 3.3 Hydrogen usage in the transport sector, socioeconomic analysis

Calculation of net present value over the period 2017-2030 of the fossil fueled vehicles is performed by utilizing the general equation below:

$$NPV_{\text{fossil}} = \sum_{i=0}^{13} \frac{\text{Costs}_{\text{emission type}}}{(1+r)^i}$$

Equation 43: General equation for the net present value of fossil fueled vehicles

Here  $r$  is the required rate of return, which in this report is assumed to be 4 % based on an expert committee's analysis of frameworks for socioeconomic analyses (88). Their estimation is based on the Government Pension Fund Global's (GPF) real rate of return of 2.5 % from government bonds plus risk premium of 1.5 % (88). One might therefore argue that the required rate of return should be decreased to 3 %, based on the GPF's required rate of return most likely being decreased from 4 % to 3 % (89). The net present value is evaluated over a period of 14 years to evaluate the compatibility with Norway's climate goals.

The socioeconomic importance of the most significant changes in the sector is evaluated. This means the transition from diesel and gasoline vehicles to hydrogen FCEVs and EVs is the focus.

The calculations in this chapter are based on the following assumptions and simplifications:

- A scenario for production costs for an arbitrary hydrogen or electric bus or heavy-duty truck based on the development of hydrogen buses given by FCH is evaluated (90). Due to ASKO director Jørn Endresen's estimates of cost compatibility between hydrogen and diesel heavy-duty trucks by the early 2020s (35), another scenario is added where governmental expenses due to purchase of hydrogen heavy-duty trucks converges to zero in 2030. Convergence by early 2020s is not included due to the major disparity in estimates by Endresen and FCH (35, 90).
- It is also assumed that this reduction in costs is mirrored in relative terms by public support awarded for purchase of such vehicles.
- For hydrogen FCEVs in each separate sector, it is assumed that 50 % more fueling stations than what is theoretically necessary must be established in order to supply all vehicles.
- In the calculations of the net present value of the hydrogen value chain, governmental expenses due to operation and maintenance of hydrogen fueling stations and distribution of hydrogen are neglected.
- The emissions of diesel and gasoline vehicles are assumed to decrease linearly by 32.5 % from 2017 to 2030. Over the period 2030-2050, emissions of diesel and gasoline vehicles are assumed to decrease linearly by an additional 25 %. This is loosely based on the Ministry of Finance's report of 2016, where the development of annual average CO<sub>2</sub>-emissions from new passenger vehicles from 2001 to 2015 is presented (91). Over these 14 years, the annual average CO<sub>2</sub>-emissions have decreased from roughly 180 to 100 g CO<sub>2</sub>/km.
- For the reference scenario of status quo prolonged, it is assumed that 55 % and 45 % of all new vehicles in the period 2017-2050 are respectively diesel and gasoline vehicles.
- The development of vehicle stocks are set from ITE's report from 2016 (68).

Statistics of emissions from passenger vehicles, cargo vans and heavy-duty trucks are collected from the Norwegian Public Roads Administration (NPRA) and shown in Table 14 (92).

| National emissions by vehicle and fuel type, 2013 |           |                                     |                             |                              |                             |                             |                   |                             |                                 |                                  |

Table 14: National emissions by vehicle and fuel type, 2013 (92)

The emission numbers of Table 14 are combined with national numbers for kilometers driven by the various vehicle and fuel types for 2016 (93), developing specific estimates for emissions per kilometer driven. The result of this is shown in Table 15.

| Emissions, by vehicle and fuel type |           |                           |                        |                        |                        |                        |                        |            |                        |            |             |

Table 15: Emissions, by vehicle and fuel type

As the NPRA did not provide numbers for buses, these are assumed to equal those of cargo vans. Additionally, as the estimates for heavy-duty trucks running on gasoline in Table 15 do not appear realistic, the numbers for heavy-duty trucks running on diesel will be used here. It is assumed that the annual amount of kilometers driven on Norwegian roads is constant over the evaluated periods. An essential factor when calculating emissions in the transport sector is the projected amount of vehicles for the time period evaluated. The Institute of Transport Economics (ITE) in Norway have made an estimate of this, the results of which are presented in Table 17 through Table 20 (68).

| Vehicle stock development, current path |         |         |         |         |         |         |         |         |
|-----------------------------------------|---------|---------|---------|---------|---------|---------|---------|---------|
| Year                                    | 2015    | 2020    | 2025    | 2030    | 2035    | 2040    | 2045    | 2050    |
| Cargo vans                              | 430170  | 475678  | 515494  | 542128  | 552762  | 556363  | 567368  | 590971  |
| Heavy duty trucks                       | 60572   | 51232   | 49183   | 48343   | 47919   | 48027   | 48556   | 49506   |
| Tractor units                           | 8506    | 10056   | 11984   | 13799   | 15495   | 16905   | 18255   | 19790   |
| Buses                                   | 16484   | 13656   | 11737   | 10586   | 10427   | 10596   | 10689   | 10688   |
| Passenger vehicles                      | 2578424 | 2758593 | 2910881 | 3074099 | 3256107 | 3449440 | 3629604 | 3759532 |

Table 16: Vehicle stock development, current path (68)

Table 16 shows vehicle stock development along the current path estimated by ITE in their current path scenario (68). It is these numbers scenario status quo prolonged is based on. The calculations in this report evaluate the period 2017-2050, and interpolation and extrapolation is performed for the years not specified by ITE.

| Passenger vehicles stock projection, by fuel |         |         |         |         |         |         |         |         |
|----------------------------------------------|---------|---------|---------|---------|---------|---------|---------|---------|
| Year                                         | 2015    | 2020    | 2025    | 2030    | 2035    | 2040    | 2045    | 2050    |
| Gasoline                                     | 1237057 | 871805  | 571155  | 329243  | 149564  | 55153   | 20049   | 7287    |
| Diesel                                       | 1220981 | 1263550 | 1020751 | 627367  | 315364  | 140470  | 59417   | 24032   |
| BEV                                          | 68995   | 377987  | 1058034 | 1901929 | 2634358 | 3159089 | 3472458 | 3607597 |
| Hydrogen                                     | 19      | 374     | 16591   | 68037   | 136801  | 206485  | 266656  | 348616  |

Table 17: Passenger vehicle stock projection, by fuel (68)

Table 17 shows the most significant changes projected by ITE in their ultra-low emissions scenario from 2015 to 2050 (68) in the passenger vehicle stock. BEVs are projected to take over most of the passenger vehicle stock, while diesel and gasoline consequently lose their shares. Hydrogen FCEVs are projected to take only a small share of the stock. The sum of passenger vehicles is projected to increase from roughly 2.58 million vehicles in 2015 to 4 million vehicles in 2050 (68). The calculations in this report evaluate the period 2017-2050, and interpolation and extrapolation is performed for the years not specified by ITE.

| Cargo vans stock projection, by fuel |        |        |        |        |        |        |        |        |
|--------------------------------------|--------|--------|--------|--------|--------|--------|--------|--------|
| Year                                 | 2015   | 2020   | 2025   | 2030   | 2035   | 2040   | 2045   | 2050   |
| Gasoline                             | 29141  | 12011  | 5517   | 2258   | 671    | 194    | 59     | 12     |
| Diesel                               | 398845 | 433172 | 369182 | 239910 | 127990 | 59124  | 27595  | 14051  |
| BEV                                  | 1805   | 30231  | 123937 | 204687 | 259778 | 304169 | 354265 | 417393 |
| Hydrogen                             | 0      | 12     | 17756  | 108291 | 205959 | 265965 | 281772 | 271450 |

Table 18: Cargo van stock projection, by fuel (68)

Table 18 shows the most significant changes projected for the cargo van stock by ITE in their ultra-low emissions scenario from 2015 to 2050 (68). Here, both BEVs and hydrogen FCEVs are projected to take close to equal and major shares of the stock, while gasoline and diesel consequently decrease significantly. The sum of cargo vans is projected to increase from roughly 430 000 to 703 000 vehicles over the time period.

| Heavy duty trucks and tractor units stock projection, by fuel |       |       |       |       |       |       |       |       |
|---------------------------------------------------------------|-------|-------|-------|-------|-------|-------|-------|-------|
| Year                                                          | 2015  | 2020  | 2025  | 2030  | 2035  | 2040  | 2045  | 2050  |
| Gasoline                                                      | 2982  | 1242  | 901   | 577   | 81    | 5     | 1     | 0     |
| Diesel                                                        | 65809 | 59360 | 55627 | 46883 | 32313 | 22398 | 15407 | 10382 |
| BEV                                                           | 2     | 1     | 0     | 0     | 0     | 0     | 0     | 0     |
| Hydrogen                                                      | 0     | 0     | 60    | 6757  | 23163 | 36321 | 46825 | 55895 |

Table 19: Heavy-duty trucks and tractor unit stock projection, by fuel (68)

Table 19 shows the most significant changes projected for the heavy-duty truck and tractor unit stock by ITE in their ultra-low emissions scenario from 2015 to 2050 (68). Here, BEVs are projected to essentially have no share. Diesel remains the dominant fuel used in this period, even though its share is halved. Hydrogen FCEVs are projected to come to the market around 2025, rapidly increasing its

share after entry. This projection is conservative, as Nikola One expect to begin delivering their trucks in 2020 (43) and ASKO as soon as 2018 will have heavy-duty trucks running on hydrogen (94). The sum of heavy-duty trucks is projected to decrease from roughly 60 000 to 58 500 vehicles, while tractor units are projected to increase from roughly 8 500 to 23 500 units. Note that here both heavy-duty trucks and tractor units are accounted for; while in the calculations in this thesis heavy-duty trucks are assumed to represent the average unit in this sector.

| Bus stock projection, by fuel |       |       |      |      |      |      |      |      |
|-------------------------------|-------|-------|------|------|------|------|------|------|
| Year                          | 2015  | 2020  | 2025 | 2030 | 2035 | 2040 | 2045 | 2050 |
| Gasoline                      | 297   | 90    | 38   | 21   | 3    | 0    | 0    | 0    |
| Diesel                        | 15498 | 12345 | 7919 | 3769 | 1493 | 639  | 263  | 142  |
| BEV                           | 11    | 171   | 1281 | 2429 | 3186 | 3741 | 4350 | 4725 |
| Hydrogen                      | 5     | 153   | 1607 | 3390 | 4841 | 5526 | 6242 | 6721 |

Table 20: Bus stock projection, by fuel (68)

Table 20 shows the most significant changes projected for the bus stock by ITE in their ultra-low emissions scenario from 2015 to 2050 (68). Hydrogen FCEVs are projected to take the largest share in this sector, closely followed by BEVs. Consequently, diesel vehicles are projected to decline from roughly 15 500 to barely 100. The amount of buses is projected to decrease from roughly 16 500 to 12 000 vehicles over the period.

### 3.3.1 Passenger vehicles

In a report published by the Norwegian Environment Agency, governmental outcome due to purchase of EVs are 70 000 NOK for a small EV and 435 000 NOK for a big EV (95). In the following calculations, it is assumed that these expenses are valid for FCEVs as well. In addition, it is assumed that governmental expenses due to purchase of EVs and hydrogen FCEVs decrease by 0.5 % for every thousand vehicles of the respective category sold. 15 % of all EVs and FCEV are assumed to be of the category ‘big’, while the remaining 85 % are assumed to be of the category ‘small’.

Through email correspondence with Tor Kjetil Bergsaker of Uno-X, it became clear that governmental expenses for one of their hydrogen stations, the “Car-200”, is 10 MNOK (96). One such station has the capacity to cover hydrogen consumption of 486.67 hydrogen vehicles. This ratio is used as basis for calculations for all hydrogen stations. It is assumed that governmental expenses connected to establishment of hydrogen stations decrease over time. The nature of this decrease is uncertain, and a range of 1-2 % reduction per hydrogen station established is used in these calculations. As hydrogen passenger vehicles will receive financial support from the government until year 2025 or until 50 000 hydrogen passenger vehicles have been purchased (91), both these scenarios are evaluated. The results are given in Figure 7 and Figure 8.

Figure 7: Net present value development for hydrogen passenger vehicles with financial support until 50 000 units and required fueling stations

Figure 7 shows the range of net present values of the costs for hydrogen passenger vehicles and required fueling stations with financial support until 50 000 units. Evaluating over the 14-year period renders net present values from -5 441 MNOK to -7 127 MNOK. The stock of hydrogen FCEVs reach 50 000 units early in year 13, meaning NPV difference from years 12 to 14 mostly comes from public financial support for fueling stations. See Appendix 1: Tables and calculations for relevant tables.

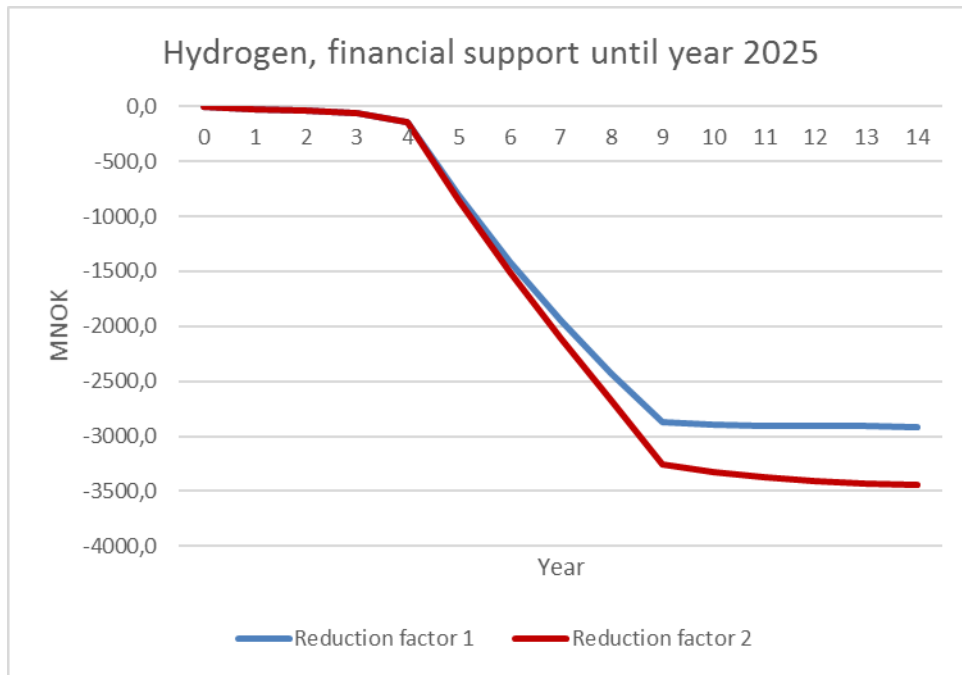

Figure 8: Net present value development for hydrogen passenger vehicles with financial support until year 2025 and required fueling stations

Figure 8 shows the range of net present values of the costs for hydrogen passenger vehicles and required fueling stations with financial support until year 2025. Evaluating over the 14-year period renders net present values from -2 913 MNOK to -3 447 MNOK. The hydrogen FCEV stock reaches 16 591 units by year 2025, which is an increase of 16 501 units from the start of 2017. The NPV difference from years 9 to 14 only comes from public financial support for fueling stations.

Figure 9: Net present value development for electric passenger vehicles with financial support until year 2020 and required rapid charging stations

Figure 9 shows the range of net present values of the costs for electric passenger vehicles with financial support until year 2020 and required rapid charging stations. Evaluating over the 14-year period renders NPVs from -14 499 MNOK to -26 929 MNOK. The EV stock reaches 377 987 units by 2020, which is an increase of 247 194 units from the start of 2017. The abrupt change from year 4 to 5 is due to purchases of EVs no longer being publicly financially supported and the assumption that governmental expenses to rapid charging stations decrease by 0.1 % for reduction factor 1 and 0.01 % for reduction factor 2 for each station established.

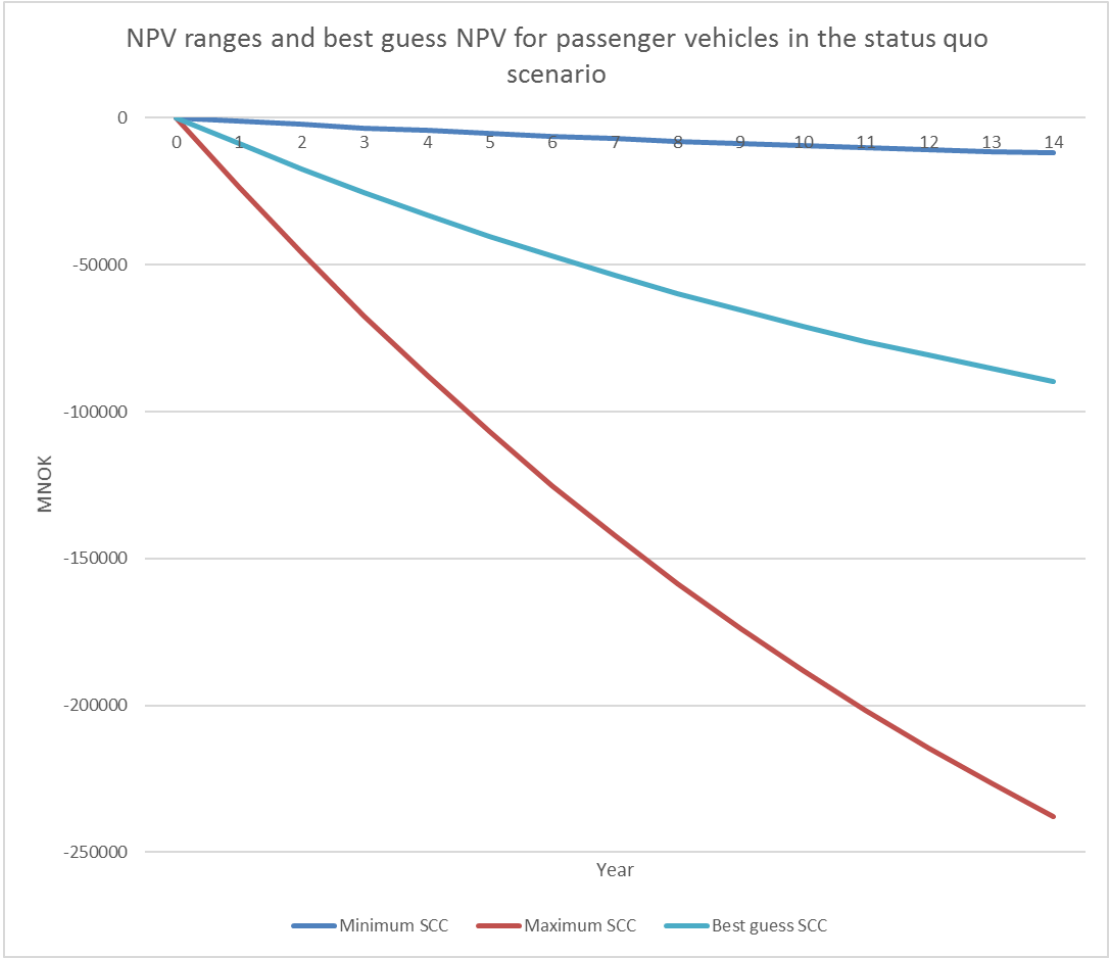

Figure 10: NPV ranges and best guess NPV for passenger vehicles in the status quo scenario

Figure 10 shows the range of net present values of the social costs of carbon in the status quo scenario. In this scenario, no zero-emission vehicles are purchased and no hydrogen fueling stations nor charging stations are established in the evaluated period. However, the total amount of passenger vehicles continues along its current path. This combined with the numbers for social and abatement costs of emissions from Table 8 and Table 9 results in the range of NPV values seen in Figure 10. The “Best guess SCC” represents estimated values based on IPCC’s “best guess” value for the social cost of CO<sub>2</sub> (97) and combined with Table 9. See Appendix 1: Tables and calculations for more details.

Combining all previously shown results from passenger vehicles, calculations can be made for the net present value of the ultra-low emission path. This is shown in Figure 11.

Figure 11: Net present value of the ultra-low emission path with evaluation period 2017-2030

The net present value of the ultra-low emission path involves great investments over the first four years, mostly due to public financial support of EV purchases. Assuming this investment causes the stock development of zero-emission vehicles to increase according to the Norwegian Institute of Transport Economics, reduction of emissions lead to this investment being socioeconomically sound when evaluating over a period of 14 years with an NPV of 5 533 MNOK when assuming minimum hydrogen FCEV and EV costs. When assuming maximum hydrogen FCEV and EV costs, the NPV of investment into the projected development is -7 431 MNOK. See Appendix 1: Tables and calculations for more details.

Calculations were also made for the period 2017-2050. These can be seen in Figure 12.

Figure 12: Net present value of the ultra-low emission path for passenger vehicles with evaluation period 2017-2050

The net present value of the ultra-low emission path involves great investments over the first four years, mostly due to public financial support of EV purchases. After these governmental expenses have ended, what remains are smaller investments in hydrogen FCEV stock, hydrogen fueling stations and rapid charging stations. Evaluating for 2017-2050 gives an NPV of 51 389 MNOK when assuming minimum hydrogen FCEV and EV costs. When assuming maximum hydrogen FCEV and EV costs, the NPV of investment into the projected development is 38 665 MNOK. See Appendix 1: Tables and calculations for more details.

### 3.3.2 Cargo vans

In the following calculations, parameters for governmental expenses due to purchase of passenger EVs from chapter 3.3.1 are assumed to be valid for electric and hydrogen cargo vans as well.

Figure 13: Net present value development for hydrogen cargo vans with financial support until 50 000 units and required fueling stations

Figure 13 shows the range of net present values of the costs for hydrogen cargo vans and required fueling stations with financial support until 50 000 units. Evaluating over the 14-year period renders net present values from -5 296 MNOK to -7 098 MNOK. The stock of hydrogen FCEVs reach 50 000 units in year 11, meaning NPV difference from years 11 to 14 only comes from public financial support for fueling stations. See Appendix 1: Tables and calculations for relevant tables.

Figure 14: Net present value development for hydrogen cargo vans with financial support until year 2025 and required fueling stations

Figure 14 shows the range of net present values of the costs for hydrogen cargo vans and required fueling stations with financial support until year 2025. Evaluating over the 14-year period renders net present values from -3 047 MNOK to -3 638 MNOK. The hydrogen FCEV stock reaches 17 756 units by year 2025, which is an increase of 17 754 units from the start of 2017. The NPV difference from years 9 to 14 only comes from public financial support for fueling stations.

Figure 15: Net present value development for electric cargo vans with financial support until year 2020 and required rapid charging stations

Figure 15 shows the range of net present values of the costs for electric cargo vans with financial support until year 2020 and required rapid charging stations. Evaluating over the 14-year period renders NPVs from -2 699 MNOK to -2 981 MNOK. The EV stock reaches 30 231 units by 2020, which is an increase of 22 741 units from the start of 2017. The abrupt change from year 4 to 5 is due to the stop of public financial support of EV purchases and the assumption that governmental expenses to rapid charging stations decrease by 0.1 % for reduction factor 1 and 0.01 % for reduction factor 2 for each station established.

Figure 16: NPV ranges and best guess NPV for cargo vans in the status quo scenario

Figure 16 shows the range of net present values of the social costs of emissions in the status quo scenario. In this scenario, no zero-emission vehicles are purchased and no hydrogen fueling stations nor charging stations are established in the evaluated period. However, the total amount of cargo vans continues along its current path. This combined with the numbers for social and abatement costs of emissions from Table 8 and Table 9 results in the range of NPV values seen in Figure 16. The “Best guess SCC” represents estimated values based on IPCC’s “best guess” value for the social cost of CO<sub>2</sub> (97) and combined with Table 9. See Appendix 1: Tables and calculations for more details.

Combining all previously shown results for cargo vans, calculations can be made for the net present value of the ultra-low emission path. This is shown in Figure 17.

Figure 17: Net present value of the ultra-low emission path with evaluation period 2017-2030

In the projected development of cargo vans from 2017-2030, the amount of vehicles is significantly smaller than that for passenger vehicles. Due to the smaller scale than and similar assumptions to the passenger vehicles sector, investments in this sector isolated do not return positive NPVs in the evaluated period. An NPV of -744 MNOK is achieved when assuming minimum hydrogen FCEV and EV costs. When assuming maximum hydrogen FCEV and EV costs, the NPV of investment into the projected development is -1 616 MNOK. See Appendix 1: Tables and calculations for more details.

Calculations were also made for the period 2017-2050. These can be seen in Figure 18.

Figure 18: Net present value of the ultra-low emission path for cargo vans with evaluation period 2017-2050

Evaluating for 2017-2050 gives an NPV of 13 533 MNOK when assuming minimum hydrogen FCEV and EV costs. When assuming maximum hydrogen FCEV and EV costs, the NPV of investment into the projected development is 12 688 MNOK. See Appendix 1: Tables and calculations for more details.

### 3.3.3 Heavy-duty trucks

In the heavy-duty trucks sector, some major assumptions are made:

- For calculation of costs of hydrogen fueling stations connected to the heavy-duty trucks sector, the reduction factor is set to 2 %.
- As no electric heavy-duty trucks are purchased in this scenario, no values are set.
- The cost of a hydrogen heavy-duty truck today is set to 7 MNOK, based on talks with the industry (35). Governmental expenses due to purchase of hydrogen heavy-duty trucks are given in Table 25. Unlike what is done for passenger vehicles and cargo vans, national scaling of heavy-duty trucks is considered to be irrelevant to governmental expenses due to purchase of such vehicles. Instead, the year of purchase is set as the significant factor.
- Hydrogen consumption of a hydrogen heavy-duty truck is calculated to be 1 635.8 kg H<sub>2</sub>/year based on average annual distance driven by diesel heavy-duty trucks from Table 15 and average hydrogen consumption of a Nikola One from Table 4.

Figure 19: Net present value development for hydrogen heavy-duty trucks with financial support until 50 000 units and required fueling stations

Figure 19 shows the range of net present values of the costs for hydrogen heavy-duty trucks and required fueling stations with financial support until 50 000 units. Evaluating over the 14-year period renders net present values from -271 MNOK to -4 825 MNOK. The stock of hydrogen FCEVs reaches 50 000 units in year 2047, which does not come into account here. The major change in governmental costs from year 9 is due to the combination of the assumption of year being the significant factor for governmental expenses due to purchase of vehicles and the stock of hydrogen heavy-duty trucks increasing from 60 to 6 757 units from year 9 to 14. See Appendix 1: Tables and calculations and Table 25 for more information.

Figure 20: Net present value development for hydrogen heavy-duty trucks with financial support until year 2025 and required fueling stations

Figure 20 shows the range of net present values of the costs for hydrogen heavy-duty trucks and required fueling stations with financial support until year 2025. Evaluating over the 14-year period renders net present values from -219 MNOK to -272 MNOK. The hydrogen FCEV stock reaches 60 units by year 2025, which is an increase of 60 units from the start of 2017. The NPV difference from years 9 to 14 only comes from public financial support for fueling stations. The jump from year 8 to 9 comes mainly from the assumption that all hydrogen fueling stations are built the year prior to when the correlating number of hydrogen FCEVs are purchased.

Figure 21: NPV ranges and best guess NPV for heavy-duty trucks in the status quo scenario

Figure 21 shows the range of net present values of the social costs of emissions in the status quo scenario. In this scenario, no zero-emission vehicles are purchased and no hydrogen fueling stations nor charging stations are established in the evaluated period. However, the total amount of heavy-duty trucks continues along its current path. This combined with the numbers for social and abatement costs of emissions from Table 8 and Table 9 results in the range of NPV values seen in Figure 21. The “Best guess SCC” represents estimated values based on IPCC’s “best guess” value for the social cost of CO<sub>2</sub> (97) and combined with Table 9. See Appendix 1: Tables and calculations for more details.

Combining all previously shown results for heavy-duty trucks, calculations can be made for the net present value of the ultra-low emission path. This is shown in Figure 17.

Figure 22: Net present value of the ultra-low emission path with evaluation period 2017-2030

In the projected development of heavy-duty trucks from 2017-2030, the amount of vehicles increases drastically from year 9 to 10. Due to the great difference between estimated development of production costs of hydrogen buses by FCH and ASKO (35, 90), the range of NPVs varies greatly. An NPV of -2 250 MNOK is achieved when using FCH’s development of hydrogen FCEV costs. When assuming a rapid decrease of FCEV costs based on FCH’s estimate and taking ASKO’s prediction into account, the NPV of investment into the projected development is 2 303 MNOK. See Appendix 1: Tables and calculations for more details.

Calculations were also made for the period 2017-2050. These can be seen in Figure 23.

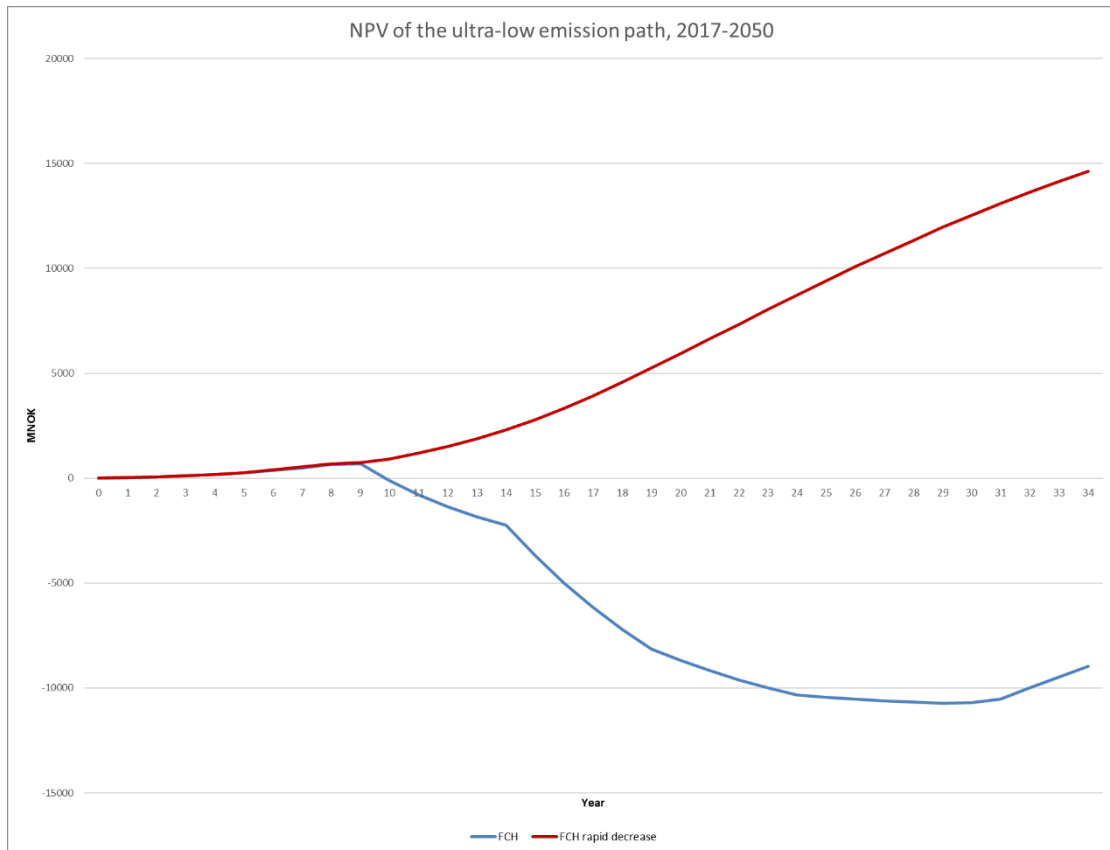

Figure 23: Net present value of the ultra-low emission path for heavy-duty trucks with evaluation period 2017-2050

Evaluating for 2017-2050 gives an NPV of 14 638 MNOK when assuming a rapid decrease of FCEV costs based on FCH’s estimate and taking ASKO’s prediction into account. When using FCH’s development of hydrogen FCEV costs, the NPV of investment into the projected development is negative 8 980 MNOK. See Appendix 1: Tables and calculations for more details.

### 3.3.4 Buses

In the bus sector, some major assumptions are made:

- For calculation of costs of hydrogen fueling stations and rapid charging stations connected to the bus sector, the reduction factors are set to 2 % and 0.1 %, respectively.
- Governmental expenses due to purchase of hydrogen buses are given in Table 25. Unlike what is done for passenger vehicles and cargo vans, national scaling of buses is considered to be irrelevant to governmental expenses due to purchase of such vehicles. Instead, the year of purchase is set as the significant factor. Due to ASKO’s prediction of cost parity between hydrogen and conventional diesel heavy-duty trucks (35), the FCH rapid decrease scenario is added to the bus sector as well.
- Governmental expenses due to purchase of electric buses are assumed to equal those of hydrogen.

- Hydrogen consumption of a hydrogen bus is calculated to be 4 231 kg H<sub>2</sub>/year based on average annual distance driven by diesel buses from Table 15 and average hydrogen consumption of a Ruter's hydrogen buses in Oslo from Table 3.
- Support for electric buses is assumed to be maintained until 2025.
- One rapid charging station is established for every 7.1 electric bus.

Figure 24: Net present value development for hydrogen buses with financial support until year 2030 and required fueling stations

Figure 24 shows the range of net present values of the costs for hydrogen buses and required fueling stations with financial support until year 2030. Evaluating over the 14-year period renders net present values from -2 686 MNOK to -501 MNOK. See Appendix 1: Tables and calculations and Table 25 for more information.

Figure 25: Net present value development for hydrogen buses with financial support until year 2025 and required fueling stations

Figure 25 shows the range of net present values of the costs for hydrogen buses and required fueling stations with financial support until year 2025. Evaluating over the 14-year period renders net present values from -1 653 MNOK to -489 MNOK. The hydrogen FCEV stock reaches 1 607 units by year 2025, which is an increase of 1 572 units from the start of 2017. The NPV difference from years 9 to 14 only comes from public financial support for fueling stations.

Figure 26: Net present value development for electric buses with financial support until year 2025 and required rapid charging stations

Figure 27 shows the range of net present values of the costs for electric buses with financial support until year 2025 and required rapid charging stations. Evaluating over the 14-year period renders NPVs from -289 MNOK to -1 202 MNOK. The EV stock reaches 1 281 units by 2025, which is an increase of 1 238 units from the start of 2017.

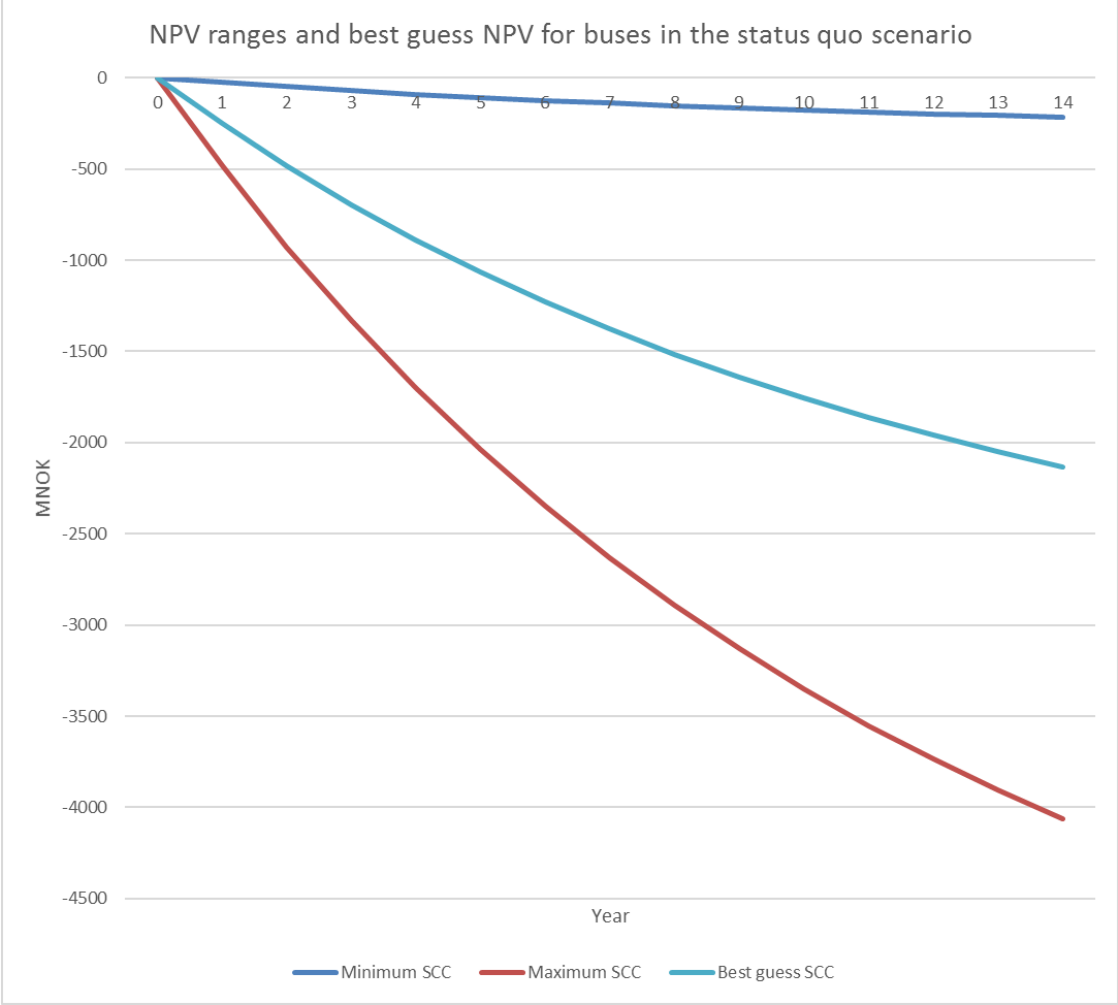

Figure 27: NPV ranges and best guess NPV for buses in the status quo scenario

Figure 27 shows the range of net present values of the social costs of emissions in the status quo scenario. In this scenario, no zero-emission vehicles are purchased and no hydrogen fueling stations nor charging stations are established in the evaluated period. However, the total amount of buses continues along its current path. This combined with the numbers for social and abatement costs of emissions from Table 8 and Table 9 results in the range of NPV values seen in Figure 27. The “Best guess SCC” represents estimated values based on IPCC’s “best guess” value for the social cost of CO<sub>2</sub> (97) and combined with Table 9. See Appendix 1: Tables and calculations for more details.

Combining all previously shown results for buses, calculations can be made for the net present value of the ultra-low emission path. This is shown in Figure 28.

Figure 28: Net present value of the ultra-low emission path with evaluation period 2017-2030

An NPV of -2 368 MNOK is achieved when using FCH’s development of hydrogen FCEV costs. When assuming a rapid decrease of FCEV costs based on FCH’s estimate and taking ASKO’s prediction into account, the NPV of investment into the projected development is -291 MNOK. The major development change seen from year 9 to 10 occurs due to purchases of zero-emission buses not receiving public financial support anymore. See Appendix 1: Tables and calculations for more details.

Calculations were also made for the period 2017-2050. These can be seen in Figure 29.

Figure 29: Net present value of the ultra-low emission path for buses with evaluation period 2017-2050

Evaluating for 2017-2050 gives an NPV of 484 MNOK when assuming a rapid decrease of FCEV costs based on FCH’s estimate and taking ASKO’s prediction into account. When using FCH’s development of hydrogen FCEV costs, the NPV of investment into the projected development is negative 1 593 MNOK. See Appendix 1: Tables and calculations for more details.

3.3.5 The whole transport sector combined

When combining the whole transport sector, it is assumed that the amount of established hydrogen fueling stations equals the theoretically necessary number due to synergy effects of hydrogen usage in all sectors.

Figure 30: Net present value development for all hydrogen vehicles with financial support until year 2030 and required fueling stations

Figure 30 shows the range of net present values of the costs for all hydrogen vehicles and required fueling stations with financial support until year 2030 for heavy-duty trucks and buses and until 50 000 units for passenger vehicles and cargo vans. Evaluating over the 14-year period renders net present values from -20 651 MNOK to -10 664 MNOK. The change in costs seen from year 9 to 10 is due to the hydrogen stocks of passenger vehicles, cargo vans and heavy-duty trucks experiencing a massive increase that year. The smaller change from year 4 to 5 is mainly due to the increase of hydrogen passenger vehicles and cargo vans. See Appendix 1: Tables and calculations and Table 25 for more information.

Figure 31: Net present value development for all hydrogen vehicles with financial support until year 2025 and required fueling stations

Figure 31 shows the range of net present values of the costs for all hydrogen vehicles and required fueling stations with financial support until year 2025. Evaluating over the 14-year period renders net present values from -7 925 MNOK to -5 823 MNOK. The change from year 4 to 5 is mainly due to the increase of hydrogen passenger vehicles and cargo vans, as can also be seen in Figure 30. The NPV difference from years 9 to 14, or lack thereof, only comes from public financial support for fueling stations.

Figure 32: Net present value development for all electric vehicles with financial support until year 2025/2020 and required rapid charging stations

Figure 32 shows the range of net present values of the costs for all electric vehicles with financial support until year 2025 for buses and year 2020 for passenger vehicles and cargo vans. Evaluating over the 14-year period renders NPVs from -30 199 MNOK to -18 401 MNOK. The NPV is mostly influenced by passenger and cargo vans, which are not given public financial support after year 2020. This is what creates the spike in year 4.

Figure 33: NPV ranges and best guess NPV for all vehicles in the status quo scenario

Figure 33 shows the range of net present values of the social costs of emissions in the status quo scenario. In this scenario, no zero-emission vehicles are purchased and no hydrogen fueling stations nor charging stations are established in the evaluated period. However, the total amount of vehicles continues along its current path. This combined with the numbers for social and abatement costs of emissions from Table 8 and Table 9 results in the range of NPV values seen in Figure 33. The “Best guess SCC” represents estimated values based on IPCC’s “best guess” value for the social cost of CO<sub>2</sub> (97) and combined with Table 9. See Appendix 1: Tables and calculations for more details.

Combining all previously shown results for all vehicles combined, calculations can be made for the net present value of the ultra-low emission path. This is shown in Figure 34.

Figure 34: Net present value of the ultra-low emission path with evaluation period 2017-2030

An NPV of -20 754 MNOK is achieved when using FCH’s development of hydrogen bus costs for bus and heavy-duty trucks costs, reduction factor 2 for passenger vehicles and cargo vans. The latter are given public financial support until 2020, while the former are given public financial support until 2030. When assuming a rapid decrease of heavy-duty truck and bus costs based on FCH’s estimate and taking ASKO’s prediction into account, in addition to using reduction factor 1 for passenger vehicles and cargo vans, the NPV of investment into the projected development becomes 2 859 MNOK. The first 4 years, cost development is dominated by EVs, while the change seen from year 9 to 11 is due to hydrogen FCEVs massively entering the market. See Appendix 1: Tables and calculations for more details.

Calculations were also made for the period 2017-2050. These can be seen in Figure 35.

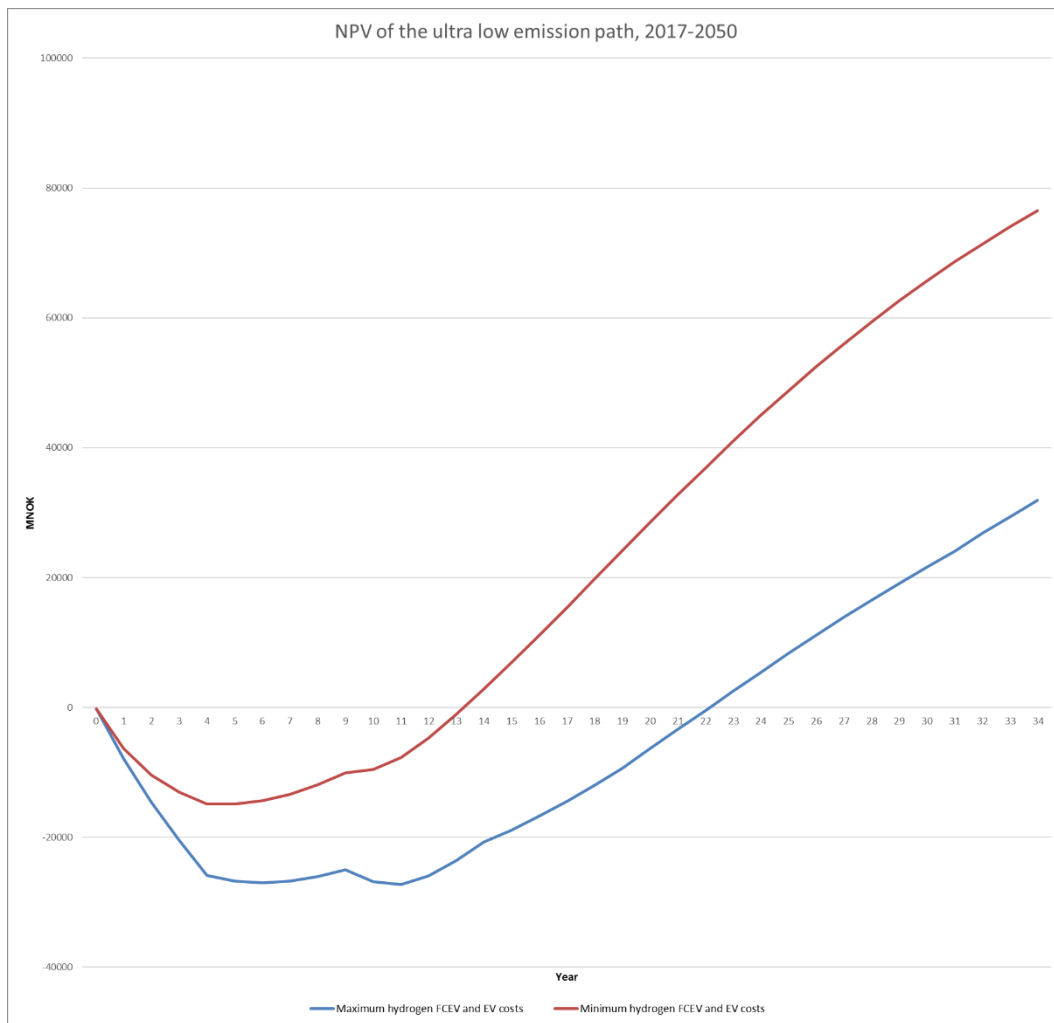

Figure 35: Net present value of the ultra-low emission path for all vehicles with evaluation period 2017-2050

An NPV of 31 887 MNOK is achieved when using FCH’s development of hydrogen bus costs for bus and heavy-duty trucks costs, reduction factor 2 for passenger vehicles and cargo vans. The latter are given public financial support until 2020, while the former are given public financial support until 2050. When assuming a rapid decrease of heavy-duty truck and bus costs based on FCH’s estimate and taking ASKO’s prediction into account, in addition to using reduction factor 1 for passenger vehicles and cargo vans, the NPV of investment into the projected development becomes 76 525 MNOK. See Appendix 1: Tables and calculations for more details.

| Cost and NPV comparisons |           |                                                  |                                                                    |                                                                      |                            |                            |

Table 21: Costs of GHG reductions and NPV comparisons of all scenarios, short version

**Important note:** The values for this table are tailored for comparison with GHG emission statistics for Norway made by Statistics Norway, in which only the emissions CO<sub>2</sub>, CH<sub>4</sub> and N<sub>2</sub>O are accounted for, while this thesis includes CO<sub>2</sub>, CH<sub>4</sub>, N<sub>2</sub>O, SO<sub>2</sub>, NO<sub>x</sub>, nmVOC, NH<sub>3</sub>, PM<sub>2,5</sub> and PM<sub>10</sub>. As such, annual GHG reduction in 2030 and 2050 only accounts for those that Statistics Norway also account for.

Table 21 shows:

- Annual GHG reduction in 2030 in tons CO<sub>2</sub>-equivalents; meaning, by investment made into a certain scenario, the expected emission reduction in CO<sub>2</sub>-equivalents by 2030 from the start of 2017. This is calculated due to Norway's climate goals being a GHG reduction of 40 % by 2030 when comparing with 1990-levels.
- GHG reduction cost 2017-2030 in NOK per ton CO<sub>2</sub>-equivalent. Meaning, how much do the GHG reductions one can expect in 2030 cost per ton CO<sub>2</sub>-equivalents for a certain scenario.
- NPV based on best guess SCC 2030 in MNOK. Meaning, what is the net present value of investment in a certain scenario when evaluating over 2017-2030 when using the best guess social costs of emissions.
- NPV based on best guess SCC 2050 in MNOK. Meaning, what is the net present value of investment in a certain scenario when evaluating over 2017-2050 when using the best guess social costs of emissions.

Conclusions from Table 21:

- Fossil fuel types, in this thesis being diesel and gasoline, will in scenario 'status quo prolonged' reduce GHG emissions by a significant amount in all sectors due to technology improvement and stock reductions. Note that passenger vehicles and cargo vans' stocks increase, while heavy-duty trucks and buses decrease. It is assumed that this development takes place without any governmental financial support. Nonetheless, social costs of emissions cause significant governmental expenses, meaning all sectors hold negative net present values for status quo prolonged.
- The various EV and hydrogen FCEV scenarios are already explained, and will not be discussed further. However, there is particularly one important aspect of these calculations that must be known: Annual GHG reduction in 2030 is calculated by multiplying the amount of zero-emission vehicles purchased from 2017-2030 in one scenario with the amount of emissions an average vehicle of the same type emits in 2016. As such, these values do not account for emissions reduced due to stock reductions and it is assumed that every purchase of a zero-emission vehicle replaces an average fossil fuel vehicle of the same vehicle type.
- The NPV values for 2017-2030 are calculated using the following formula:

$$NPV_{i,j} = NPV_{Investmenti,j} - NPV_{Replaced,j}$$

*Equation 44: NPV of scenario i in sector j*

In Equation 44,  $NPV_{\text{Investment},i,j}$  is the NPV of governmental expenses due to investment in scenario  $i$  and sector  $j$  evaluated from 2017-2030 and  $NPV_{\text{Replaced},j}$  is the NPV of the diesel and gasoline vehicles in sector  $j$  evaluated from 2017-2030 multiplied with the ratio of zero-emission vehicles in scenario  $i$  in 2030 to the total amount of vehicles in sector  $j$  in 2030.

- The NPV values for 2017-2050 are calculated using Equation 44 for 2017-2050 instead of 2017-2030.

### 3.4 Implications for Norway

In this chapter, the transition to a zero-emission society and its implications for Norway in the light of the results of this thesis is analyzed.

#### 3.4.1 CCS

The development of CCS technology and competence has great export potential. In the EU alone, if CCS is integrated in existing waste incineration plants, 60-70 million tons of CO<sub>2</sub> emissions can be averted (98). Considering energy recovery being a globally growing industry, this number should grow. Norway has considerable potential of becoming a significant exporter of CCS technology and competence (99). The market for this technology in the future will be vast if global warming is to be limited to 2 °C, as agreed upon in Paris (2). Simultaneously, the global demand for energy is to rise, mainly causing an increase in natural gas usage and some increase in oil usage (100). In this scenario, Norway's income levels are not threatened in the near future by the transition to a zero-emission society as the demand for oil and natural gas increases, and thus the demand for Norwegian oil and gas should not decrease. In addition, if this scenario comes to be, it is not likely that the emissions of the national fossil fuel industry will decrease quickly enough for Norway to have a decent chance of reaching its climate goals of 40 % emission reduction by 2030. The most apparent solution in this scenario is to implement large scale CCS nationally and aim for export of technology and competence from this area.

In a scenario where the implementation of renewable solutions continues its fast development, causing demand for fossil fuels, including natural gas, to decline, Norway's income levels are threatened in the near future by the transition to a zero-emission society as the demand for oil and natural gas will decline. The decrease in demand increases financial risks connected to investments in the fossil industry, and increases need for new sources of income for Norway if its standard of living is to be maintained. Development of CCS is also in this scenario necessary if global warming is to be limited to 2 °C, though less critical than in the high emission scenario discussed above, as the complete implementation of renewable solutions is very unlikely to occur soon enough for this to keep global warming limited to 2 °C (63).

In 2015, global emissions amounted to 11.2 Gt carbon (101). This number is converted to CO<sub>2</sub>-equivalents in Equation 45:

$$\text{Emissions}_{\text{Global},2015} = 11.2 \text{ Gt C} \cdot \frac{M_{\text{CO}_2}}{M_{\text{C}}} = 11.2 \text{ Gt C} \cdot \frac{44 \frac{\text{g}}{\text{mol}}}{12 \frac{\text{g}}{\text{mol}}} = \underline{41.1 \text{ Gt CO}_2}$$

*Equation 45: Global emissions of 2015 in Gtons CO<sub>2</sub>*

The average emissions from 2006-2015 amounted to 10.3 Gt C/year, which converted to Gt CO<sub>2</sub>/year as in Equation 45 equals 37.8 Gt CO<sub>2</sub>/year (101).

IPCC report that by 2011, 1 900 GtCO<sub>2</sub> had been emitted by human activities (97). This leaves a budget of approximately 1 000 GtCO<sub>2</sub> to be consistent with the goal of limiting global warming to 2 °C (97).

Utilizing the average emissions between 2011 and 2015, the carbon budget remains at 848.8 Gt CO<sub>2</sub> at the beginning of 2015. Using global emissions from 2015 for 2015 and 2016 means the remaining carbon budget from 2017 and onwards amounts to 766.6 Gt CO<sub>2</sub>.

The amount of CO<sub>2</sub>-equivalents which must be stored in order to not blow the carbon budget is given in Equation 46:

$$S_{\text{CO}_2} = \sum_{2017}^{2100} E_{\text{Global,Annual}} - 766.6 \text{ Gt CO}_2$$

*Equation 46: Amount of stored CO<sub>2</sub>-equivalents required to not exceed the carbon budget*

The amount of CO<sub>2</sub>-equivalents actually emitted from 2017 is very uncertain. Many reports have been published on the matter, and most present roughly the same scenarios. IPCC's scenarios range from annual GHG emissions reaching zero in approximately 2080 in RCP2.6 to emissions increasing and exceeding 100 GtCO<sub>2</sub>/year in 2080 in RCP8.5 (97). Basing calculations on limiting global warming to 2 °C, i.e. RCP2.6, a linear approximation from today's emissions of 41.1 GtCO<sub>2</sub>/year to zero-emissions in 2080, 63 years from 2017, means total emissions amount to 1 294.7 GtCO<sub>2</sub>. The total amount of stored CO<sub>2</sub>-equivalents becomes

$$S_{\text{CO}_2,\text{RCP2.6}} = (1294.7 - 766.6) \text{ Gt CO}_2 = \underline{528.1 \text{ Gt CO}_2}$$

*Equation 47: Total amount of stored CO<sub>2</sub>-equivalents by the RCP2.6 scenario*

This estimate does not take into account whether or not it is practically possible to capture this amount of CO<sub>2</sub>. An example of this not being viable is in the transport sector.

Norway's CO<sub>2</sub> storage potential accumulates to roughly 86.15 Gt CO<sub>2</sub> (55-57). Based on IPCC's predictions, large scale CCS must be established regardless of it being neither socioeconomically nor commercially viable if global warming is to be limited to 2 °C (53).

Crucial for this industry to thrive without governmental financial support, is that the price on CO<sub>2</sub> increases to a point where this industry becomes commercially viable (53).

### 3.4.2 The transport sector

As presented in Table 21, by following ITE's ultra-low emissions path, there is potential for annual reduction of GHG emissions in 2030 of 3.37 Mt CO<sub>2</sub>-equivalents for electric vehicles in the transport sector. For hydrogen FCEVs in the transport sector, there is potential for annual reduction of GHG emissions in 2030 of roughly 183 000 tons CO<sub>2</sub>-equivalents. With 2015's total emissions amounting to 10.3 Mt CO<sub>2</sub>-equivalents (5), this transition represents a reduction of 34.5 % from 2015-2030. However, Norway's climate goals state a reduction of 40 % by 2030 with respect to 1990-levels, which in the transport sector amounted to 7.77 Mt CO<sub>2</sub>-equivalents. With basis in ITE's ultra-low emissions path, the transport sector reduces emissions by roughly 13 % with respect to 1990-levels. If Norway is to uphold its climate goals with this development in the transport sector, other sectors must decrease emissions by far more. This is contradictory to the Norwegian Environment Agency's claims that the greatest potential for emission reductions for sectors not subject to the quotas trading system lies in the transport sector (102).

## 4 Discussion

In the following, the analyses made in this thesis will be discussed separately.

### 4.1 The TiZir case

In TiZir Titanium & Iron's transition from using coal to using hydrogen as a chemical component in their production process, only SMR and water electrolysis are considered as viable options in this thesis. As both technologies are well known, assuming no technical difficulties in establishment nor operation appears natural.

When discussing which solution represents the best investment case, the perspective from which the discussion is made is important. Here, it is natural to separate between TiZir's, Norway's and the climate goals perspective.

#### *TiZir's perspective*

From TiZir's perspective, the most natural factor to start with is price. Based on the results from this thesis, the scale of which TiZir requires means water electrolysis represents an economically more reasonable choice than SMR. In addition, when considering the development of CO<sub>2</sub>-taxations, costs are most likely to increase. How significant this increase will be is very unclear and subject to a vast number of variables. Not least of which is political.

Another factor, which TiZir might be concerned with, is their company's carbon footprint. There is potential for climate friendly commodities being more attractive on the market than others, meaning the market might be willing to pay more solely based on a commodity being a climate friendly product. If this is the case, water electrolysis is more beneficial than SMR.

Another aspect, which might become relevant, is the fact that global warming acts as a disruptor on the weather systems we know today. As a result, there is potential for escalated frequency of weather occurrences leading to loss of power grid stability and thus hydrogen production stability if using water electrolysis.

#### *Norway's perspective*

Norway's interests in this situation are assumed to be the reduction of GHGs, development of technology and creating jobs.

When considering the potential of GHG reduction, there are two aspects: Direct reduction from TiZir's facility and repercussions from TiZir's transition. When looking at direct reduction of GHGs, it is clear that water electrolysis represents the greater reduction. Note that this would not be the case if

Norway's electricity production was not mostly based on hydro power. Repercussions from TiZir's transition for SMR involve establishment of CCS infrastructure which can be used for other projects as well. Additionally, such a project could increase national actors' competence on CCS, which on the long term can be very useful if global warming is to be limited to 2 °C. For electrolysis, it represents the potential of massively reducing hydrogen production costs due to the large scale. A scenario exists where production capacity is increased to some extent, enabling sale of hydrogen to other sectors, such as the transport and maritime sector. It also represents increased competence on renewable hydrogen production, which can be exported. Job creation appears greater if using SMR, due to the massive infrastructure project necessary to facilitate CCS.

### *Climate goal*

Both solutions represent GHG reductions in their own way. Directly, electrolysis causes a greater reduction than SMR. However, establishment of large scale CCS has potential for great reduction of GHGs nationally and globally. On another note, special adviser for Norwea, Andreas Aasheim, claims that CCS would be a waste of resources if invested for use in the energy production sector due to renewable energy prices declining rapidly (103).

## 4.2 Hydrogen usage in the transport sector, socioeconomic analysis

In this chapter, the socioeconomic analyses of hydrogen usage in the transport sector are discussed. First, the assumptions and simplifications made in the calculations are considered. Second, the results of the analyses are discussed.

### *Assumptions and simplifications*

In the analysis of hydrogen usage in the transport sector, biofuels are not included. As such, the analysis does not cover enough to give a complete understanding of the socioeconomic benefits of investment in hydrogen FCEVs and EVs.

The development of vehicle stocks are set from ITE's report from 2016 (68). Since the scaling of a certain vehicle type's stock has a great impact on its net present value, the NPV is somewhat predetermined by the used projections for development of vehicle stocks. For a more accurate understanding of hydrogen's potential in the transport sector, the analysis should be set free from stock development projections. If this is done, it is possible to estimate which specific vehicle stock development represents the greatest socioeconomic return on investment. In such a case however, one might achieve results, which require unlikely stock developments.

Assumption of governmental expenses due to purchase of electric passenger vehicles is based on the Norwegian Environment Agency's estimates (95). For hydrogen passenger vehicles, hydrogen and

electric cargo vans, heavy-duty trucks and buses, these were assumed or estimated. Proper values for these parameters could increase the accuracy of the results of this report significantly.

The disparity of cost parity estimates between Endresen and FCH cause some uncertainty as to when cost parity can actually be expected to occur (35, 90). This is reflected in the NPVs of heavy-duty trucks and buses. While the ranges of NPVs of passenger vehicles and cargo vans are quite small, the ranges of NPVs of heavy-duty trucks and buses are rather large.

The numbers for emissions by vehicle and fuel type are for 2013. These can be seen in Table 14. They are combined with values for distances driven by vehicle and fuel type, which are for 2015. These can be seen in Table 15. This obviously causes wrong numbers for emissions to be used in this thesis and most likely is the reason why gasoline heavy-duty trucks' emission values are so high. Therefore, they are not used. Using values from the same year would definitely increase accuracy of the results of this report.

Some of the best guess abatement and social costs of emissions are averages of the respective minimum and maximum values. See Table 24 for more details. These averages, in addition to the use of minimum abatement costs for CH<sub>4</sub> and N<sub>2</sub>O, represent potential weaknesses of the legitimacy of the best guess costs actually being the best guess.

For hydrogen FCEVs, the reduction factor of 2 % for each hydrogen fueling station established and for every thousandth hydrogen vehicle purchased is a value, which is not based on any previous works, only the fact that commercialization of hydrogen FCEVs has just began. Since commercialization of EVs began 5-10 years ago, they are given smaller reduction factors.

In one scenario, buses and heavy-duty trucks are assumed to be given public financial support until 2050. This is done because of the major disparity between estimates of cost parity between renewable and non-renewable versions of these vehicles.

In the status quo prolonged scenario, it is assumed that 55 % and 45 % of all new vehicles in the period 2017-2050 are respectively diesel and gasoline vehicles. This is used as a reference scenario. It does not represent reality, rather a worst-case scenario where the government does not have any further expenses due to zero-emission vehicles, charging stations nor fueling stations. Thus, calculating NPVs which, use the NPVs of status quo prolonged scenarios, do not give completely accurate results.

All hydrogen FCEVs and EVs are assumed to be bought at the very end of their respective year of purchase. As such, no emissions are reduced by the purchase of a zero-emission vehicle until the year after purchase. This is incorrect, and the accuracy of the results would be better if actual conditions for this were taken into account.

Purchases of hydrogen passenger vehicles are signaled by the Norwegian government to be given public financial support until 2025 or until 50 000 units have been purchased. Both these cases have been analyzed. Considering the stock is estimated to reach 50 000 units after 2025, it appears most likely that public financial support will cease after 2025. Therefore, this is what is included in the NPVs for projected developments.

Purchases of zero-emission cargo vans are assumed to be given the same governmental financial support as those for passenger vehicles. Most likely, this value should be increased.

Governmental expenses due to purchase of electric buses are assumed to equal those of hydrogen buses. This is most likely not accurate.

In the calculations of the NPVs of hydrogen FCEVs and EVs shown in Table 21, the NPVs of the status quo scenarios are divided by the total number of vehicles of a given sector of the final year of evaluation. This is done in order to get values for how much money one hydrogen FCEV or EV saves society. This is inaccurate because if the stock decreases in the period of evaluation, then money saved per vehicle is increased to more than it should be. Also vice versa, if the stock increases in the period of evaluation, then money saved per vehicle decreases to less than it should be. The latter is the case for electric passenger vehicles for instance. As such, the NPV of electric passenger vehicles would be higher if this simplification was not made. Additionally, with the same logic, the NPVs of hydrogen heavy-duty trucks would be smaller if this simplification was avoided.

The NPVs with investments into zero-emission vehicles are compared with the status quo scenarios, which are the worst-case scenarios. In reality, if there were no more governmental expenses due to purchase of zero-emission vehicles nor fueling or charging stations, the EV and hydrogen FCEV stock would still continue to increase somewhat due to prior investments. Thus, future sales of vehicles would not only be of diesel and gasoline. As such, the more realistic scenario represents less savings due to investments in zero-emission vehicles. The extent of which is unclear.

The emissions of fossil fueled buses are assumed to equal those of fossil fueled cargo vans. This is most likely less than what is realistic, which portrays zero-emission buses as less beneficial than they should be. The reason for this is that every zero-emission bus is estimated to displace fewer emissions than it in reality would.

The calculations are not as accurate and thus the curve is not as smooth as it could have been due to linear interpolation between the five year intervals of stock values collected from the ITE (68).

Cost development due to scaling of hydrogen FCEVs and EVs is only based on national stock development, not global development. Given the small share of hydrogen FCEVs in the passenger

vehicle sector, the cost development of hydrogen FCEVs does not decrease as rapidly as what might become reality. Depending on the development of the global share of hydrogen FCEVs, governmental expenses due to purchase of said vehicles might be greater or less than what is assumed in this thesis.

### *Analyses*

Even in the status quo scenarios, which are the worst-case scenarios, technology development causes fossil fuel vehicles to reduce annual GHG emissions in 2030. Assuming this development causes no governmental expenses in and of itself, this significant emission reduction has no direct costs for Norway. However, by accounting for social costs of emissions, the NPVs of making no investments in the transport sector show this to be very costly for the Norwegian society. In the case of all combined from 2017-2050, the cost of doing nothing ranges from 37.5 to 677.5 billion NOK, with 270 billion NOK being the estimate from the best guess SCCs.

Meanwhile, the NPVs of investments into hydrogen FCEVs and EVs are in this thesis for the most part estimated to save the Norwegian society money in the 2050-perspective with best guess SCCs. Electric passenger vehicles are the ones projected to reduce annual GHG emissions in 2030 by the largest amount. Also, with the smallest cost and the best NPV both in 2017-2030 and in 2017-2050. Hydrogen's best results come from heavy-duty trucks and buses, where they are calculated to achieve better NPVs overall than EVs. An important note to make is this: the main reason behind electric passenger vehicles' superior NPVs vs. the others is because of the large share of electric passenger vehicles projected by ITE. Meaning, the purchases of electric passenger vehicles are only given governmental financial support until 2020, with the repercussion still being that the passenger vehicle sector in 2050 mostly consists of EVs. This fact does not, however, discredit the legitimacy of the NPV of electric passenger vehicles of roughly 110-120 billion NOK. No other sector is projected to experience the same repercussion, though hydrogen heavy-duty trucks come close with their 60-80 billion NOK.

A very interesting thing to note is that even though hydrogen heavy-duty trucks do not provide the highest NPV, they do provide the lowest overall GHG reduction cost. This is, unless hydrogen heavy-duty truck purchases are given public financial support until 50 000 units are purchased and the cost development of the units follow the prediction of FCH. However, even if that is the case, it is still a sound investment as the net present value clearly shows.

Overall for hydrogen investments, when looking at all combined, only one of 12 cases shows a negative NPV. This case is based on the maximum cost development, the maximum amount of units purchased, which are publicly financially supported, and the minimum social costs of emissions. With fair certainty, it can be established that the Norwegian society will benefit from investments into hydrogen vehicles, with the largest benefits coming from heavy-duty trucks and cargo vans.

Overall for investments into electric vehicles, when looking at all combined, only one of 6 cases shows a negative NPV. This case is also based on the maximum cost development, the maximum amount of units purchased which are publicly financially supported and the minimum social costs of emissions. In addition, it is certain that the Norwegian society will benefit from investments into electric vehicles, with the largest benefits coming from passenger vehicles and cargo vans.

### 4.3 Implications for Norway

CCS is a challenging technology. Many environmentalists do not wish for large scale CCS due to fear that it will become an excuse for more intensive extraction of fossil resources. For businesses, it is not an attractive option due to low CO<sub>2</sub>-taxes (53). Socioeconomically it is deemed unviable (53). Scientists are also arguing whether the technology of CCS is good enough to ensure no leakage of the stored CO<sub>2</sub> (52).

However, the question is if global warming can be kept under or to 2 °C without CCS. Aasheim seems to think the energy production sector can hold their own in this matter due to renewable energy prices declining rapidly (103). If IPCC's projections for a 2 °C scenario are correct (97), one might need to store or find some other use for 528.1 Gt CO<sub>2</sub>.

In a world where all or most countries account for the social costs of emissions, CCS becomes a much more attractive alternative than it is today. If this is the case, then Norway might have a substantial source of income in storage of other nations' CO<sub>2</sub>. Perhaps the first step in this direction would be to work for a global price on CO<sub>2</sub>.

As for Norway's own climate goals, the GHG reductions analyzed in this thesis only amount to roughly 13 % reduction of the transport sector's emissions in the period 2017-2030 with respect to 1990-levels. If the transport sector is to reduce more than the other sectors (102), relatively, then annual emissions here must be reduced by at least an additional 2.1 Mt CO<sub>2</sub>-equivalents by 2030. As such, ITE's projections for the transition to a zero-emission society do not hold in a climate goals perspective, and must be escalated.

### 4.4 Overall considerations

Biofuels are not included in this thesis. Biofuels must reduce emissions by a minimum of 35 % today, and will be increased to a minimum of 50 % by 2018 with respect to fossil fuels when the whole value chain for the biofuel is included (104). As Norwegian political parties focus on biofuels as a good environmental measure, inclusion of these would bear some significance (91). It is unclear how much, if any, governmental expenses would be required to develop a market for this in Norway. The benefit and costs of biofuels depends heavily on this.

Norway is world leading in fossil fuel technologies. This fact gives this country great potential to continue development within CCS. By this, one can generate more export of technology and competence while the export of fossil commodities decreases and thus not suffer a loss of welfare in Norway. Our great competence within fossil fuel technologies could also make the transition to a zero-emission society and becoming world leading in renewable technologies a path of little resistance.

On the very long term, even the utilization of CCS in waste treatment might become obsolete, as manufacturing of products at some point could become a closed-loop supply chain (105). However, this does not mean that CCS is not worth developing.

In a report by RethinkX , the author claims that by 2030, 95 % of all passenger miles in the U.S. will be served by transport-as-a-service providers (106). This means most people will not be in possession of their own vehicle. This is a very important piece of information when planning for the future. The question is, however, if it changes the results obtained in this report in case this should also be valid for Norway? One could argue that it does not, based on the following assumptions:

1. The number of passenger miles is independent of ownership of vehicle.
2. Large scale implementation of this solution does not impact the number of EV and hydrogen FCEV purchases granted public financial support.

Based on assumption number 1, the fuel/energy consumption in an ideal system should be unaffected by most people not being in possession of their own vehicle. As such, the amount of fueling stations should also be unaffected by this and thus the governmental expenses for fueling stations. By assumption 2, governmental expenses from purchases of EVs and hydrogen FCEVs remain unaffected by this solution. What might influence governmental expenses is the fact that such a solution presents potential for a much more rapid transition towards a zero-emission stock of vehicles. If this is the case, one might see a significant decrease in governmental expenses due to pollution from fossil fueled vehicles which weakens the socioeconomic argument for financially supporting EVs and hydrogen FCEVs.

ITE's report does not take into account increased usage of car sharing and increased market share for companies like Uber (68). These represent solutions potentially pushing the car stock downwards, as fewer and fewer people need to own their own vehicle with these solutions. The scale on which these solutions will be implemented globally is unclear, especially in lesser-developed countries.

## 5 Conclusion

Hydrogen is a promising energy carrier for Norway in the transition to a zero-emission society. Norway should not limit its efforts to either renewable hydrogen or fossil hydrogen with CCS. Both technologies should be focused on. However, costs of solar and wind power are rapidly decreasing. CCS is not socioeconomically viable, not attractive due to low CO<sub>2</sub>-taxes and there is uncertainty as to whether the technology is good enough or not. It is therefore concluded in this thesis that hydrogen produced with fossil fuels at best is as good as hydrogen produced with energy from renewable sources. The uncertain factors connected to hydrogen produced from fossil energy sources imply great investment risks on the long term.

Even without the increase of costs related to emission of CO<sub>2</sub>, which means CCS remains economically unviable, it is still strongly suggested that further development of this technology is pursued. This is based on IPCC's statements about CCS being necessary for limiting global warming to 2 °C.

The key findings in this thesis are given in the following five paragraphs:

Hydrogen produced by water electrolysis is the economically better choice for TiZir. It is also the better choice in terms of carbon footprint and risk of increased CO<sub>2</sub>-taxes. Socioeconomically, water electrolysis represents the greater reduction of GHGs, while SMR represents more jobs created. In development of technology, the alternatives are considered equal. Overall, water electrolysis is the recommended solution in the TiZir case.

Hydrogen's most beneficial role in the Norwegian transport sector is estimated to lie with heavy-duty trucks where the socioeconomic net present value amounts to 60-80 billion NOK evaluated from 2017-2050. Cargo vans also represent a good investment case. Due to lack of data on buses, it cannot be concluded that the Norwegian society will benefit similarly from investments into hydrogen buses. However, it is found to be likely that this is also the case.

Norway benefits greatly socioeconomically on investments into the transition from fossil fueled vehicles to zero-emission vehicles. The costs of doing nothing are potentially tremendous.

CCS most likely is necessary to some extent if global warming is to be limited to 2 °C. However, global unity is required for this to become a relevant industry.

Norway's climate goals will not be met if escalated actions are not taken based on the GHG reductions found in this thesis.

## 6 Suggested further work

For further work on this matter, the number of simplifications used in the calculations needs to be reduced. The key assumptions and simplifications given in the following should be addressed.

This thesis' basis on ITE's projections should be removed. This is due to NPVs being dependent on scale of purchase of vehicles as well as the vehicles' potency in itself.

Biofuels should be included in the analysis such that a wider understanding of the socioeconomic benefits of investments can be reached.

Governmental expenses due to purchases of zero-emission vehicles should be further researched as these impact results greatly.

Estimates on cost development of heavy-duty trucks and buses vary greatly. The range of these should be shortened.

## Appendix 1: Tables and calculations

### *Common tables and calculations*

In the following, tables and calculations relevant for calculations of all or several sectors are presented.

| Vehicle stock development, current path |         |         |         |         |         |         |         |         |
|-----------------------------------------|---------|---------|---------|---------|---------|---------|---------|---------|
| Year                                    | 2015    | 2020    | 2025    | 2030    | 2035    | 2040    | 2045    | 2050    |
| Cargo vans                              | 430170  | 475678  | 515494  | 542128  | 552762  | 556363  | 567368  | 590971  |
| Heavy duty trucks                       | 60572   | 51232   | 49183   | 48343   | 47919   | 48027   | 48556   | 49506   |
| Buses                                   | 16484   | 13656   | 11737   | 10586   | 10427   | 10596   | 10689   | 10688   |
| Passenger vehicles                      | 2578424 | 2758593 | 2910881 | 3074099 | 3256107 | 3449440 | 3629604 | 3759532 |

*Table 22: Vehicle stock development, current path*

Table 22 shows vehicle stock development for the current path scenario. This table is developed by the Norwegian Institute of Transport Economics' report and is used as basis for calculation of gasoline and diesel net present values (68). Linear interpolation is performed as the report only includes estimates for every fifth year (68).

| Emissions, by vehicle and fuel type |           |                           |                           |                        |                        |                        |                        |                        |             |                        |            |             |
|-------------------------------------|-----------|---------------------------|---------------------------|------------------------|------------------------|------------------------|------------------------|------------------------|-------------|------------------------|------------|-------------|
| Vehicle type                        | Fuel type | Million kilometers driven | Average annual km/vehicle | kg CO <sub>2</sub> /km | kg CH <sub>4</sub> /km | kg N <sub>2</sub> O/km | kg SO <sub>2</sub> /km | kg NO <sub>x</sub> /km | kg NMVOC/km | kg NH <sub>3</sub> /km | kg PM10/km | kg PM2,5/km |

Table 23: Emissions and distance driven, by vehicle and fuel type

Table 23 shows emissions and distance driven, by vehicle and fuel type. These numbers for emissions are collected from the Norwegian Public Roads Administration (92) for 2013, combined with numbers for distances driven which are collected from Statistics Norway (93) for 2015. As stated in chapter 3.3.3, the numbers for emissions for heavy-duty trucks running on gasoline appear to be wrong, thus the numbers for diesel are used here instead. This is likely to be due to the combination of 2015 and 2013 numbers.

Table 24: Abatement and social costs of emissions, SFT and IPCC

Table 24 shows abatement and social costs of emissions based on SFT and IPCC's numbers (64, 97). The values with colored background are the ones used for the best guess scenarios. The ones with yellow background are values directly collected from either SFT or IPCC's reports, while the ones with red background are averages of the respective maximum and minimum values. Combined with the assumptions mentioned in chapter 3.3, all NPVs for diesel and gasoline vehicles are developed. These are not further explained, but the results are listed under their respective sector.

For hydrogen FCEV calculations, the following values are commonly used among the sectors:

- Governmental expenses connected with establishment of a hydrogen fueling station today is 10 MNOK. Such a station has the capacity to produce 200 kg H<sub>2</sub>/day, which translates to roughly 73 000 kg H<sub>2</sub>/year.
- A reduction factor is used in the calculations. This amounts to a reduction of marginal governmental expenses connected with establishment of hydrogen fueling stations by 2 % for each hydrogen fueling station established and a reduction of marginal governmental expenses connected with purchases of hydrogen vehicles by 2 % for every thousandth hydrogen vehicle purchased. For situations where several thousand hydrogen vehicles

are bought within a single year, it is assumed that governmental expenses due to purchase of these vehicles is equal for all hydrogen vehicles bought that year and the reduction factor used is based on the number of hydrogen vehicles at the end of that year in that sector. For passenger vehicles and cargo vans, two different reduction factors are used. See respective sector for further information.

- Financial support for purchase of hydrogen FCEVs is signaled by the Norwegian government to last until a stock of 50 000 units is achieved or until 2025, whichever comes first (91). Both of these scenarios are evaluated for all sectors, even though this only is meant to apply to passenger vehicles and in all cases a stock of 50 000 units is only achieved after 2025.

For EV calculations, the following values are commonly used among the sectors:

- Governmental expenses due to establishment of a rapid charging station today is 600 000 NOK (95).

Table 25: Vehicle costs and public financial support development, buses and heavy-duty trucks [MNOK]

Table 25 shows vehicle costs and public financial support development for buses and heavy-duty trucks. These estimates are based on projected costs of hydrogen buses by The Fuel Cells and Hydrogen Joint Undertaking (FCH JU) (90). Row one in Table 25 uses these projected costs with interpolation as the FCH report only gives values for every fifth year. The initial value for the public financial support is set to be half of the cost difference between the hydrogen buses and the conventional diesel buses. The cost of conventional diesel buses in 2015 was 2.179 MNOK (90).

For hydrogen heavy-duty trucks, ASKO states that one such truck costs 7 MNOK (35). It is assumed that the cost ratio between diesel and hydrogen heavy-duty truck is the same as for diesel and hydrogen buses. By this assumption, the cost of a diesel heavy-duty truck is 2.558 MNOK. The initial value for the public financial support for heavy-duty trucks is set to be half of the cost difference between the hydrogen and diesel heavy-duty trucks.

Due to ASKO director Jørn Endresen's estimates of cost compatibility between hydrogen and diesel heavy-duty trucks by the early 2020s (35), another scenario is added where governmental expenses due to purchase of hydrogen heavy-duty trucks converges to zero in 2030. Convergence by early 2020s is not included due to the major disparity in estimates by Endresen and FCH.

### *Passenger vehicles*

The following assumptions and values are used in these calculations:

- For hydrogen FCEVs, the reduction factors 1 and 2 are set to respectively 2 % and 1 %.
- For EVs, the reduction factors 1 and 2 are set to respectively 0.1 % and 0.01 %. The basis for this is that EVs have a significantly greater market share than hydrogen vehicles, making it natural that cost reductions in this sector does not occur as dramatically as for hydrogen vehicles.
- Initial value for governmental expenses due to purchase of EVs and hydrogen FCEVs are set to respectively 124 750 NOK and 249 500 NOK. This is based on values from a report of the Norwegian Environment Agency stating that governmental expenses due to purchase of EVs amount to 70 000 NOK for a small EV and 435 000 NOK for larger EVs (95), in addition to the assumption that 15 % of all EVs are large EVs and 85 % of all EVs are small EVs.
- Hydrogen consumption of a hydrogen FCEV passenger vehicle is assumed to be 150 kg H<sub>2</sub>/year based on talks with the industry (96).
- Support for electric passenger vehicles is assumed to be maintained until 2020, which is what the Norwegian government signals (91).
- One rapid charging station is sufficient to cover the consumption of 200 EVs.

Table 26: Passenger vehicles stock development, by fuel (68)

Table 26 shows passenger vehicles stock development for the ultra-low emissions scenario. This table is developed by the Norwegian Institute of Transport Economics' report and is used as basis for calculation of EVs and hydrogen FCEV's net present values (68). Linear interpolation is performed as the report only includes estimates for every fifth year (68).

Table 34: Status quo prolonged, passenger vehicles, maximum costs (IPCC)

Table 34 shows the cash flow and NPV of the scenario status quo prolonged when evaluating over the period 2017-2050 and using maximum social costs of emissions based on IPCC's report (97). These values for the social costs of emissions can be seen in Table 8.

Table 36: Projected development, passenger vehicles, best guess costs (IPCC & SFT combined)

Table 36 shows the NPV of projected development of passenger vehicles with best guess social and abatement costs of emissions in the ultra-low emissions path relative to the status quo path. This means that in year 1, being 2017, CO<sub>2</sub>-emissions are decreased by an amount worth 193 MNOK compared to what they would be in the reference scenario. Over the evaluated period, the amount of diesel and gasoline passenger vehicles becomes smaller and smaller, increasing the difference between the projected stock's emissions and the emissions of the stock in the status quo scenario and thus similarly decreasing governmental expenses due to social costs of emissions. For hydrogen FCEVs, the scenario of financial support until year 2025 and reduction factor 1 is used. For EVs, reduction factor 1 is used.

## Cargo vans

In these calculations, all assumptions equal those of passenger vehicles, with the exception of reduction factor 1 and 2 for electric cargo vans. Here, it is assumed that governmental expenses decrease by a range of 0.1-0.5 % for each thousandth vehicle purchased.

Table 37: Cargo vans stock development, by fuel

Table 26 shows passenger vehicles stock development for the ultra-low emissions scenario. This table is developed by the Norwegian Institute of Transport Economics' report and is used as basis for calculation of EVs and hydrogen FCEV's net present values (68). Linear interpolation is performed as the report only includes estimates for every fifth year (68).

| Hydrogen - cargo vans, support until 50 000 units. Table 44: Status quo prolonged, cargo vans, minimum costs (IPCC)

Table 44 shows the cash flow and NPV of the scenario status quo prolonged when evaluating over the period 2017-2050 and using minimum social costs of emissions based on IPCC's report (97). These values for the social costs of emissions can be seen in Table 8.

Table 46: Status quo prolonged, cargo vans, best guess costs (IPCC & SFT combined)

Table 46 shows the cash flow and NPV of the scenario status quo prolonged when evaluating over the period 2017-2050 and using best guess social costs of emissions based on IPCC's report (97). These values for the social and abatement costs of emissions can be seen in Table 24.

Table 47: Projected development, cargo vans, best guess costs (IPCC & SFT combined)

Table 47 shows the NPV of projected development of cargo vans with best guess social and abatement costs of emissions in the ultra-low emissions path relative to the status quo path. This means that in year 1, being 2017, CO<sub>2</sub>-emissions are decreased by an amount worth 10 MNOK compared to what they would be in the reference scenario. Over the evaluated period, the amount of diesel and gasoline cargo vans becomes smaller and smaller, increasing the difference between the projected stock's emissions and the emissions of the stock in the status quo scenario and thus similarly decreasing governmental expenses due to social costs of emissions. For hydrogen FCEVs, the scenario of financial support until year 2025 and reduction factor 1 is used. For EVs, reduction factor 1 is used.

## Heavy-duty trucks

The following assumptions and values are used in these calculations:

- For hydrogen heavy-duty trucks, the reduction factor is set to 2 %.
- As no electric heavy-duty trucks are purchased in this scenario, no values are set.
- The cost of a hydrogen heavy-duty truck is set to 7 MNOK, based on talks with the industry (35). Governmental expenses due to purchase of hydrogen heavy-duty trucks are given in Table 25.
- Hydrogen consumption of a hydrogen heavy-duty truck is calculated to be 1 635.8 kg H<sub>2</sub>/year based on average annual distance driven by diesel heavy-duty trucks from Table 15 and average hydrogen consumption of a Nikola One from Table 4.

Table 48: Heavy-duty trucks stock development, by fuel

Table 48 shows passenger vehicles stock development for the ultra-low emissions scenario. This table is developed by the Norwegian Institute of Transport Economics' report and is used as basis for calculation of EVs and hydrogen FCEV's net present values (68). Linear interpolation is performed as the report only includes estimates for every fifth year (68). Note that these values include both heavy-duty trucks and tractor units, but in calculations for this sector made in this thesis all vehicles are assumed to be heavy-duty trucks.

Table 52: Hydrogen heavy-duty trucks, support until year 2025, FCH rapid decrease

Table 52 shows the cash flow and NPV of investment into hydrogen heavy-duty trucks when evaluating over the period 2017-2050, with financial support maintained until year 2025. Development of governmental expenses due to purchase of hydrogen heavy-duty trucks are calculated with basis in FCH’s estimates, which are previously explained.

| Status quo prolonged - heavy-duty trucks, minimum costs (IPCC) |                  |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |   |

Table 53: Status quo prolonged, heavy-duty trucks, minimum costs (IPCC)

Table 53 shows the cash flow and NPV of the scenario status quo prolonged when evaluating over the period 2017-2050 and using minimum social costs of emissions based on IPCC's report (97). These values for the social costs of emissions can be seen in Table 8.

Table 55: Status quo prolonged, heavy-duty trucks, best guess costs (IPCC & SFT combined)

Table 55 shows the cash flow and NPV of the scenario status quo prolonged when evaluating over the period 2017-2050 and using best guess social costs of emissions based on IPCC's report (97). These values for the social and abatement costs of emissions can be seen in Table 24.

Table 56: Projected development, heavy-duty trucks, best guess costs (IPCC & SFT & FCH)

Table 56 shows the NPV of projected development of heavy-duty trucks with best guess social and abatement costs of emissions in the ultra-low emissions path relative to the status quo path. This means that in year 1, being 2017, CO<sub>2</sub>-emissions are decreased by an amount worth 12 MNOK compared to what they would be in the reference scenario. Over the evaluated period, the amount of diesel and gasoline heavy-duty trucks becomes smaller and smaller, increasing the difference between the projected stock's emissions and the emissions of the stock in the status quo scenario and thus similarly decreasing governmental expenses due to social costs of emissions. For hydrogen FCEVs, the scenario of financial support until 50 000 units and FCH is used. EVs have no share in this sector.

Table 57: Projected development, heavy-duty trucks, best guess costs (IPCC & SFT & FCH rapid decrease)

Table 57 shows the NPV of projected development of heavy-duty trucks with best guess social and abatement costs of emissions in the ultra-low emissions path relative to the status quo path. For hydrogen FCEVs, the scenario of financial support until 50 000 units and FCH rapid decrease is used. EVs have no share in this sector.

## Buses

The following assumptions and values are used in these calculations:

- For hydrogen buses, the reduction factor is set to 2 %.
- For electric buses, the reduction factor is set to 0.1 %.
- Governmental expenses due to purchase of hydrogen buses are given in Table 25. It is assumed that governmental expenses due to purchase of electric buses also equal these values.
- Hydrogen consumption of a hydrogen bus is calculated to be 4 231 kg H<sub>2</sub>/year based on average annual distance driven by diesel buses from Table 15 and average hydrogen consumption of a Ruter's hydrogen buses in Oslo from Table 3.
- Support for electric buses is assumed to be maintained until 2025.
- One rapid charging station is established for every 7.1 electric bus.

| Bus stock projection, by fuel |       |       |      |      |      |      |      |      |

Table 58: Bus stock development, by fuel

Table 58 shows bus stock development for the ultra-low emissions scenario. This table is developed by the Norwegian Institute of Transport Economics' report and is used as basis for calculation of EVs and hydrogen FCEV's net present values (68). Linear interpolation is performed as the report only includes estimates for every fifth year (68).

Table 62: Hydrogen buses, support until year 2025, FCH rapid decrease

Table 62 shows the cash flow and NPV of investment into hydrogen buses when evaluating over the period 2017-2050, with financial support maintained until year 2025. Development of governmental expenses due to purchase of hydrogen buses are calculated with basis in FCH's estimates, which are previously explained.

Table 68: Projected development, buses, best guess costs (IPCC & SFT & FCH)

Table 68 shows the NPV of projected development of buses with best guess social and abatement costs of emissions in the ultra-low emissions path relative to the status quo path. This means that in year 1, being 2017, CO<sub>2</sub>-emissions are decreased by an amount worth 1.7 MNOK compared to what they would be in the reference scenario. Over the evaluated period, the amount of diesel and gasoline buses becomes smaller and smaller, increasing the difference between the projected stock's emissions and the emissions of the stock in the status quo scenario and thus similarly decreasing governmental expenses due to social costs of emissions. For hydrogen FCEVs and EVs, the scenario of financial support until year 2025 and FCH is used.

Table 69: Projected development, buses, best guess costs (IPCC & SFT & FCH rapid decrease)

Table 69 shows the NPV of projected development of buses with best guess social and abatement costs of emissions in the ultra-low emissions path relative to the status quo path. For hydrogen FCEVs and EVs, the scenario of financial support until year 2025 and FCH rapid decrease is used.

*The whole transport sector combined*

The following assumption is used in these calculations other than the ones stated in the respective sectors:

- The amount of established hydrogen fueling stations equals the theoretically necessary number due to synergy effects of hydrogen usage in all sectors.

| Hydrogen - all combined, support until 50 000 units/year 2050 & reduction factor 1 & FCH rapid decrease |                          |          |       |       |       |        |         |         |         |         |         |         |         |         |        |        |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |  |

*Table 70: Hydrogen all combined, support until 50 000 units/year 2050, reduction factor 1, FCH rapid decrease*

Table 70 shows the cash flow and NPV of investment into all hydrogen vehicles when evaluating over the period 2017-2050, with financial support for passenger vehicles and cargo vans maintained until a stock of 50 000 units is achieved for each sector. For heavy-duty trucks and buses, financial support is maintained until year 2050. However, FCH rapid decrease causes this to reach zero in year 2030.

| Hydrogen - all combined, support until 50 000 units/year 2050 & reduction factor 2 & FCH |                          |        |       |       |       |        |        |        |       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |      |     |     |     |

Table 78: Status quo prolonged, all combined, best guess costs (IPCC & SFT combined)

Table 78 shows the cash flow and NPV of the scenario status quo prolonged when evaluating over the period 2017-2050 and using best guess social costs of emissions based on SFT and IPCC's report (64, 97). These values for the social and abatement costs of emissions can be seen in Table 24.

Table 79: Projected development, all vehicles, best guess costs (IPCC & SFT combined) & maximum hydrogen FCEV and EV costs

Table 79 shows the NPV of projected development of all vehicles with best guess social and abatement costs of emissions in the ultra-low emissions path relative to the status quo path with maximum hydrogen FCEV and EV costs. This means that in year 1, being 2017, CO<sub>2</sub>-emissions are decreased by an amount worth 217 MNOK compared to what they would be in the reference scenario. Over the evaluated period, the amount of diesel and gasoline vehicles becomes smaller and smaller, increasing the difference between the projected stock's emissions and the emissions of the stock in the status quo scenario and thus similarly decreasing governmental expenses due to social costs of emissions. Thusly, Table 79 combines Table 78, Table 75 and Table 71 along with the actual emissions in the ultra-low emissions path.

Table 80: Projected development, all vehicles, best guess costs (IPCC & SFT combined) & minimum hydrogen FCEV and EV costs

Table 80 shows the NPV of projected development of all vehicles with best guess social and abatement costs of emissions in the ultra-low emissions path relative to the status quo path with minimum hydrogen FCEV and EV costs. Thusly, Table 80 combines Table 78, Table 74 and Table 70 along with the actual emissions in the ultra-low emissions path.

| Cost and NPV comparisons |           |                                                  |                                                                    |                                                                      |                                                                           |                                                                                  |                                                                    |                                                                      |                                                                           |                                                                                  |                                      |                            |                         |                         |                            |                         |

Table 81: Costs of GHG reductions and NPV comparisons of all scenarios

**Important note:** The values for this table are tailored for comparison with GHG emission statistics for Norway made by Statistics Norway, in which only the emissions CO<sub>2</sub>, CH<sub>4</sub> and N<sub>2</sub>O are accounted for (5), while this thesis includes CO<sub>2</sub>, CH<sub>4</sub>, N<sub>2</sub>O, SO<sub>2</sub>, NO<sub>x</sub>, nmVOC, NH<sub>3</sub>, PM<sub>2,5</sub> and PM<sub>10</sub>. As such, annual GHG reduction in 2030 and 2050 only accounts for those which Statistics Norway also account for.

Table 81 shows:

- Annual GHG reduction in 2030 in tons CO<sub>2</sub>-equivalents. Meaning, by investment made into a certain scenario, how many tons CO<sub>2</sub>-equivalents can be expected to be reduced in 2030 from the start of 2017. This is calculated due to Norway's climate goals being a GHG reduction of 40 % by 2030 when comparing with 1990-levels.
- GHG reduction cost 2017-2030 in NOK per ton CO<sub>2</sub>-equivalent. Meaning, how much do the GHG reductions one can expect in 2030 cost per ton CO<sub>2</sub>-equivalents for a certain scenario.
- Accumulated GHG reduction 2017-2030 in tons CO<sub>2</sub>-equivalents. This is included because it is not enough to the carbon budget to see how many tons CO<sub>2</sub>-equivalents are decreased by 2030, rather the accumulated CO<sub>2</sub>-equivalents.
- Accumulated GHG reduction cost 2017-2030 in NOK per ton CO<sub>2</sub>-equivalent. Meaning, how much do the accumulated GHG reductions cost per ton CO<sub>2</sub>-equivalents for a certain scenario.
- Annual GHG reduction in 2050 in tons CO<sub>2</sub>-equivalents. This is calculated because at 2050 Norway should be getting close to a zero-emission transport sector.
- GHG reduction cost 2017-2050 in NOK per ton CO<sub>2</sub>-equivalent. Meaning, how much do the GHG reductions one can expect in 2050 cost per ton CO<sub>2</sub>-equivalents for a certain scenario.
- Accumulated GHG reduction 2017-2050 in tons CO<sub>2</sub>-equivalents. This is included because it is not enough to the carbon budget to see how many tons CO<sub>2</sub>-equivalents are decreased by 2050, rather the accumulated CO<sub>2</sub>-equivalents.
- Accumulated GHG reduction cost 2017-2050 in NOK per ton CO<sub>2</sub>-equivalent. Meaning, how much do the accumulated GHG reductions cost per ton CO<sub>2</sub>-equivalents for a certain scenario.

- NPV based on minimum SCC 2030 in MNOK. Meaning, what is the net present value of investment in a certain scenario when evaluating over 2017-2030 when using the minimum social costs of emissions.
- NPV based on best guess SCC 2030 in MNOK. Meaning, what is the net present value of investment in a certain scenario when evaluating over 2017-2030 when using the best guess social costs of emissions.
- NPV based on maximum SCC 2030 in MNOK. Meaning, what is the net present value of investment in a certain scenario when evaluating over 2017-2030 when using the maximum social costs of emissions.
- NPV based on minimum SCC 2050 in MNOK. Meaning, what is the net present value of investment in a certain scenario when evaluating over 2017-2050 when using the minimum social costs of emissions.
- NPV based on best guess SCC 2050 in MNOK. Meaning, what is the net present value of investment in a certain scenario when evaluating over 2017-2050 when using the best guess social costs of emissions.
- NPV based on maximum SCC 2050 in MNOK. Meaning, what is the net present value of investment in a certain scenario when evaluating over 2017-2050 when using the maximum social costs of emissions.
